This simple coate hath fibres of all kinds, right, oblique and transuerse, if not for his owne priuate nourishment, to which the attracting, retayning, and expelling faculties are seruicable; yet for a common vse to retayne and draw the blood (which is the treasure of Nature) from the neighbour veynes, to transmit the same from one to another and so to make distribution: finally to separate the pure from that which is impure. I thinke also sayth *Laurentius* that the fibres were ordayned *ad συνπαθήειαν*, that is to auoyde an inconuenience. For because oftentimes the blood aboundeth in quantity and offereth a kinde of violence to the veynes, sometime by right, sometime by oblique, sometime by transuerse extensions; the veynes stood in neede of all kindes of fibres, that they might bee so extended according to all the violent occurrsions and impressions made by the blood, for otherwise they would certainly be broken. These fibres are the first, most simple and truely solyd particles of the veine, but the substance which filleth vpe or stuffeth out the spaces betwixt the fibres is called fleshy by Analogy or proportion.

The fibres of the veynes sayth *Galen* in his second booke *de temperamentis*, are colder then the skinge, but the flesh that commeth betwixt them is hotter. Hence it appeareth, that the coate of the veyne differs much from the nature of other membranes, as of the *Peritonaeum* or rimme of the belly, the *Pleura* which compasseth the ribs and the *Periosteum* which immediatly inuesteth the bones: for these are indeed simple having no separated fibres, and may be torne or divided every way as paper may. But the coate of the veynes is dissimilar because it hath both fibres and flesh.

The common
coate of the
veines.

This proper coate of the Veines is inuested oftentimes with another called a *Common coate* which it borroweth from the neighbour partes, from the *Pleura* the Veines of the Chest doe borrow, and from the *Rimme* those in the lower belly. I said they haue often a *Common coate*, for all veines haue it not; for example, those that are sprinkled thorough some bowell, those that wander through the bodies of Muscles, and finally those which are inserted into the parts and in them are propagated or encreased: for such a membrane would hinder the blood that it should not so readily sweat through. Those Veines onely haue this common coate, which either doe runne a long journey, or lye vpon some hard body, or at some place are suspended or hung to any particular part: & such is the structure of a Veine.

The common
use of the
veins.

The beginning of the Veines, the Definition sayeth is the Liuer, not a beginning of generation or *originall*, (for that is the common worde though the first I thinke bee better) for all the parts are formed together: But of *Radiation* and *Dispensation*. Of *Radiation*, because the roots of the gate and hollow veines are sprinkled through the whole *Parenchyma* or flesh of the Liuer according to that of *Hippocrates* in his Booke de *Alimento*, *ἐξ ὧν οὐλεβα ἡνταρ* the *Radiatio of the Veines is the Liuer*. Of *Dispensation*, that is, of distribution and office, because from it a common matter (to wit the blood which is the common Aliment of all the parts) is deriued into the Veines; wherefore by *Hippocrates* it is called *ἰναλὸν* the fountaine and originall of pleasant and benigne humour.

The last particle of the Definition designeth the common vse and action of the Veines, for they are set apart to leade or transport, to distribute or apportion and to boyle the blood. But why this is so and how it commeth to passe, I will now addresse my selfe to declare.

CHAP. II.

Of the Vse and Action of the Veines.

BEcause the threefold substance which is in euery particular part issuing from the originals or principles of our generation, doth continually waste and suffer detriment; Nature who is studious of her owne conseruation, by a perpetuall affluence of Aliment laboureth to restore and make good that which is so necessarily spent and depopulated. The common Aliment of the parts is the blood, which all the Veines do draw from the Liuer as out of a common *magazine* or store-house. Now the blood could not be transported from the Liuer to those parts which are most distant and remote from it, vnlesse those parts had some continuity with the fountaine.

It was therefore necessary that there should bee made and formed certaine canales (as it were water-pipes) bored, to containe, conserue and conduct the blood throughout the whole body. Such are the Veines which *Aristotle* calls the vessels or conceptacles of blood. The blood therefore is containd in the Veines as in his proper place, and as the Elements in their proper places receiue no alteration; (for *the place is the conseruer of the thing placed*) so the blood within the Veines retaineth his benigne nature, but out of the Veines it presently either putrifieth or caketh.

There is therefore in the Veines an inbred power to containe and preserue the blood, which also is their primary vse. Another vse that the Veines haue is to distribute the blood; which distribution is performed by an action, that is, by attraction or drawing from the neighbour Veines, and by transmission or transportation vnto others, and for this action sake were the right and circular fibres of the veines ordayned.

Hippocrates in his Booke *De Alimento* maketh mention of a third vse of the Veines, & that is to leade along heate and spirits into the particular parts. And thence it is that though the Arteries be tyed, the partes doe not presently *sphacelate* or mortifie, because by the Veines there is an influence of a double heate and spirit, that is to say, Vitall and Naturall. The Vitall they receiue from the Heart by the wonderfull Anastomoses or inoculations of the Arteries; the Naturall they draw directly from the Liuer. By this influent spirit the inbred *Genius* of euery part is roused vp and quickned, and by it as by a good Manciple is the nourishment conueyed into the whole body.

The last vse of the Veines (which must bee referred also to their common action) is the alteration of the blood, for they are qualified to coyne and change the blood, some to prepare it as the Mesentery, others to perfect it as the great branches of the hollow veine. And this faculty or qualification they haue from the Liuer by *Irradiation*, as the Seminary vessels haue from the Testicles that power which they call *σπερματικὴ δύναμις*.

There are also other particular vses of priuate Veines; as of the Emulgents to conuay the Serous or wheyie humor; of the seede vessels to giue a rudiment vnto seede: of the *Mesaraicks* to alter the *Chylus* and to transport it to the Liuer; of the venall or short vessel to belch out melancholy iuyce into the cavity of the stomacke for the prouoking of appetite; of the veynes of the wombe to exclude the surpluse of blood at certaine and determinate periods; of the veines of the spleene to purge *seculent* or drossy blood, and so of the rest: for particulars we shall better handle in the following discourse.

Hippocrates the Oracle of Physicke, from the habit and structure of the veynes, drewe many and those notable signes of the state of the whole body. Those that haue broade Veines, sayth hee, haue also broade bellies and broade bones, for, because the blood through the veines is diuided into the whole body, wee may well make estimation of the plenty and temper of the bloode by the amplitude or straytnesse of the Veynes. They that haue much blood are esteemed hot, for their veynes are large. If the veynes bee narrow and slender, *Aristotle* accounteth them cold. They that haue much flesh haue small veynes, red blood, and little bellies and bowels: on the contrary, they that haue little flesh haue large Veynes, blacke blood, greate bowels, and side wombes or bellies. Finally by the veynes the whole body hath a kind of connexion or coherence, whence it is that they are called common ligaments.

The necessity
of the veines.

Their first vse.

The second.

The third.

The fourth.

Peculiar vses
of priuate
veines.

Table 1. Sheweth the hollow veine, whole and freed from the whole Body.

TABVLA I.

A, The trunk of the hollow veine, the lower *AA*, At this place of the Liver, is seated the left part of the veine, and distributeth branches to the left side.

B, Sheweth how the trunk of the hollow veine in the chest (to giue way to the heart) is curved or bowed to the right hand.

Betwixt A, and B, that part of the hollow veine which is betwixt the Gibbous side of the Liver and the Midriff.

C, the left midriff veine called *Phrenica sinistra*, from which furcles doe runne in a man vnto the purse of the heart, for the midriff and it doe grow together.

D, the orifice of the hollow veine which groweth vnto the heart.

E, the crown veine called *coronaria*, which like a crowne compasseth the basis of the heart, and sprinkleth his furcles on the outside thereof as farre as to the cone or point.

FF, the trunk of the veine, *Azygos* or *non parill*, descending along the right side of the racke-bones vnto the loynes.

GG, the lower intercostall veines, to the branches of the veine *Azygos*, which goe vnto the distances betwixt the ribs, & afford furcles vnto the muscles which lye vpon the ribs and the racke-bones, and the membranes of the chest.

H, the diuision of the hollow veine into 2 subclavian trunks neare the Iugulum vnder the brest-bone.

II, the subclavian branch tending on eyther side vnto the arme, called by some *Axillaris*.

K, the vpper intercostall veine which

commonly sendeth three slips vnto the distances of the vpper ribs, vnto which the first intercostall veine sent no branches. *LL*, the descending mammary veine: this descendeth vnder the brest-bone vnto the right muscles of the *Abdomen*, and affordeth furcles to the distances of the griffles of the true ribs, to the Mediastinum, the muscles that lye vpon the breast and the skinne of the *Abdomen*. *M*, the coniunction of the mammary with the Epigastricke veine ascending about the Nauill vnder the right muscles. *N*, the veine of the necke called *Cervicalis*, ascending toward the Scull which alloweth furcles to those muscles that lye vpon the necke. *O*, the veine called *Muscula*, which is propagated with many furcles into the muscles that occupy the lower parts of the necke and the vpper parts of the chest. *P*, *Thoracica superior*, the vpper chest veine which goeth to the muscles lying vpon the chest, to the skinne of that place and to the dugges. *Q*, the double *Scapularis* distributed into the hollow part of the shoulderblade and the neighbour muscles; so also betwixt *P* and *R*, sometimes small veines do reach vnto the glandules that are in the arme-holes. *R*, *Thoracica inferior* running downward along the sides of the chest, and especially distributed into the muscle of the arme called *Latissimus*. *S*, the inner Iugular veine which entreth into the Scull after it hath bestowed some furcles vpon the rough artery. *T*, the externall Iugular veine. *V*, The diuision of this veine vnder the roote of the eare. *X*, A branch of the externall Iugular which goeth into the inside of the mouth, and is diuersly diuided into the parts therein contained. *Y*, the exterior branch distributed neare the *Fances* into the muscles of the chops and the whole skinne of the head. *Z*, A portion of the branch, reaching vnto the Face. *aa*, the veine of the fore-head, a portion of it creeping through the temples *a*, * A propagation that goeth vnto the skinne of the Nowle or *Occiput*. *aa* The veine called *Cephalica*, or the externall veine of the arme which others call *Humeraria*. *b* *Muscula superior*, A propagation of the *Cephalica* veine which goeth vnto the backward muscles of the necke. Betwixt *b* and *d* on the backside islueth a branch from the *Cephalica* which passeth vnto the outside of the blade, and a portion thereof runneth betwixt the flesh and the skin. *d* *d*, A veine from the *Cephalica* which attaineth vnto the top of the shoulder, and is consumed into the muscle that eleuateth or lifteth vp the arme

and into his skinne. *cc* A small veine from the *Cephalica* dispersed through the skinne and the muscles of the arme. *f*, The diuision of the *Cephalica* into three parts. *g*, The first branch runneth deepe vnto the muscles which arise out of the externall Protuberation of the arme. *h*, The second branch which goeth to make the *median* veine. *ii*, The third branch running obliquely aboue the wand and the outside of the arme. *k*, From this branch certayne furdles are diuided into the skinne, the chiefe whereof is marked with *k*. *l*, The third branch at the wrist which is ioyned at *l*, with the branch of the *Basilica* marked with *x*. *m*, The *Basilica* which on the right hand is called *Hepatica*, on the left hand *Lienaris*. *no*, A branch of the *Basilica* going to the heads of the muscles of the cubit at *n*, and to the muscles themselves at *o*. *p*, A notable branch of the *Basilica* running obliquely, and bestowing furdles vpon the muscles that yssue from the externall protuberation. This branch descendeth together with the fourth nerue. *q*, Thdiuision of the *Basilica* into two branches, and that that is noted with *q*, is euer accompanied with an arterie. *r*, A branch of this veine bestowed vpon the the skinne of the arme. *s*, A branch of the *Basilica* which together with the branch of the *Cephalica* marked with *h*, makes the *mediana* or middle veine marked with *a*. *u*, A branch of the *Basilica* going to the inner head of the arme. *xx*, A branch issuing out of the former that creepeth along vnto the skinne at the outside of the cubit. *yy*, A propagation issuing out of a branch of the *Basilica* marked with *r*. *z*, A branch of the *Basilica* *xx*, going to the inside of the arme. *a*, The *Median* or common veine. *b*, The partition of the median veine aboue the wrist, this diuision should haue bene made aboue *y*. *y*, The externall branch of the partition which goeth to the outside of the head. *z*, From which issueth a small branch to the inside. *e*, The internall branch vnder *e*, which toward the middle and the ring finger is especially disposed. *g*, The veine of the thumbe dispersed into his mountenet or hillock which is conioyned with the branch noted with *z*. *z*, The trunk of the hollow veine from which issue branches vnto the parts seated vnder the liuer. *n*, The fatty veine called *Adiposa sinistra* which goeth vnto the fat of the kidnies. *th*, The two Emulgents which leade wheyey blood vnto the kidnies. *mu*, The two spermatieall veines leading the matter of the feede vnto the testicles. *V*, The beginning of the bodden vessell called *vas varicosum*. *z*, The veines of the loynes called *Lumbares* which are sent in knots or knees to the rackebones, to the marrow of the backe, to muscles that lie vpon the loynes, and to the *Peritoneum*. *o*, The bifurcation of the hollow veine into the black branches, which bifurcation is not vnlike *Δ*. *π*, *Muscula superior*, a transuerse branch going to the muscles of the *Abdomen* and to the *Peritoneum*. *ρ*, The diuision of the left blacke veine into an inner branch at *ρ*, and an vtter at *σ*. *τ*, *Muscula media* the vtter propagation of the branch *ρ* distributed through the muscles of the *coxa* and the skinne of the buttockes. *υ*, An inner propagation of the same branch *ρ* which goeth vnto the holes of the holy bone. *φ*, The veine called *Sacra* which goeth to the vpper holes of the holy-bone. *χ*, The veine *Hypogastrica* distributed to the bladder, to the muscles of the fundament, and the necke of the wombe. *ω*, A veine arising from the vtter branch marked with *σ* which is ioyned with some branches of the internall veine, neare the holes or perforations of the sharebone. *ε*, A veyne which when it hath passed the sharebone distributeth one branch into the cup of the *coxendix* and to the muscles of that place. *κ*, Another small branch which runneth vnder the skinne at the inside of the thigh. *ζ*, The congresse or meeting of the foresaid veine with a branch marked with *char. 2*, and distributed into the legge. *ι*, The *Epigastricke* veine, a propagation of the vtter branch *σ* perforating the *Peritoneum*, whereto as also to the muscles of the *Abdomen* and the skinne it offereth branches, the chiefe branch of this veine is ioyned with the descending mammarie aboue the nauell at *M*. *Δ*, *Pudenda* an inner propagation of the branch *σ*, running ouerthwart vnto the priuities. *Θ*, *Saphena* or the ankle veine or the inner branch of the crurall trunk, which creepeth through the inside of the legge vnder the skinne vnto the tops of the toes. *Α*, The first interior propagation of the *Saphena* offered to the groine. *Ξ*, The vtter propagation thereof diuided to the foreside or outside of the thigh. *Π*, The second propagation of the *Saphena* going to the first muscle of the legge. *Σ*, The third propagation of the *Saphena* going to the skinne of the whirlebone, and vnto the Hamme. *Φ*, The fourth propagation of the *Saphena* dispersing his muscles forward and backward. *Ψ*, Branches from this vnto the foreside of the inner ankle, to the vpper part of the foote, and to all the toes. *Ω*, *Ischias minor* called also *muscula interior*, the vtter branch of the crurall trunk diuided into the muscles of the *coxendix*, and to the skinne of that place. *1, 2*, And this also may be called *muscula*, the exterior and lesser which passeth into some muscles of the legge: *2*, the interior greater and deeper vnto the muscles of the thigh. *3, 4*, The veine called *Poplitea*, made of two crurall veines diuided vnder the knee. *5*, From this a furdle is reached vward vnto the skinne of the thigh. *6*, But the greater part runs by the bent of the knee vnder the skinne as farre as to the heele. *7*, Also to the skinne of the outward ankle. *8*, The veine called *Suralis* or calfe veine, because it runneth vnto the muscles that make the calfe of the legge. *9*, The diuision of the *Suralis* veine into an exterior trunk *9*, and an interior *14, 10, 11*, The diuision of the exterior trunk vnder the knee into an externall branch, which along the brace attayneth vnto the muscles of the Foote *11*, and in internall. *12, 13, 12, 13*, Which descending along the outside of the legge to the vpper part of the Foote is clouen into diuers branches, and in the backe of the Foote mixeth it selfe with *Poplitea*, or the hamme veine *20*. *14*, The interior branch of the *Suralis* veine which runneth into the backside of the legge. *15*, A branch hereof descending to the inside of the heele and the great toe & is diuided into diuers furdles. *17*, *Ischias maior* issuing out of the internal trunk at *14*, and running through the muscles of the calfe. *18*, A propagation hereof deriued vnto the vpper part of the foote, and affording two furdles to euery toe. *19*, The remainder of the inner trunk *14*, behinde the inner ankle, approacheth to the bottome of the Foote and is consumed into all the toes. *20*, the commixtion of the veine *Poplitea* with the *suralis* or Calfe-branch at *13*.

are

vena Azygos or the *nonparell*. Others haue companions, as almost all the rest. Others againe are solitary, that is, haue no artery accompanying them, as the veine of the arme which is called *Humeraria*, others haue arteries bearing them company.

This by the way wee must obserue, that the veines are more and greater then the arteries, because they containe a thicker Aliment and more cloudy spirit.

From the situation a veine is sayd to bee vpper and lower, ascendent, descendent; right left; externall, internall; so the splenicke branch is called *sinister* the left, the mesentericke *dexter* the right. So *Hippocrates* in his Booke *De victus ratione in acutis*, calleth the *Basilica venam internam*, the internall veine, because it runneth through the inside of the cubit, and the *Humeraria* he calleth *externam*, because it runneth on the outside.

In respect of their office or function, some veines are called *Emulgentes* the suckers because they sucke and separate wheyie humours; others *spermatice*, because they giue the seede a rudiment.

In respect of the parts through which they run, the veines haue diuers names, *Jugulares*, *Phrenica*, *Renales*, *Iliaca*, *Hypogastrica*, *Epigastrica*, *Axillares*, *Humeraria*, *Crunales*, *Poplitea*, *Asalleoli*, &c. because they run through the sticking place, the midriffe, the kidneyes, the hanches, the watercourse, the lower belly, the arme pits, the armes, the legs, the hammes and the ankles.

But because you might haue, as it were, in one view all the veines of the body, to know their deriuations, we haue to this chapter annexed a table which exhibiteth the course of the hollow veine from the crowne of the head to the soale of the foote, and the description adioyned thereto, which will poynt out euery particular. As for the skin veines how they appeare on the surface of the whole body, you haue also a generall view of them in the eight chapter of the second Booke, and therefore we will not repeate their Tables in this place, but descend vnto the particular history, beginning with the gate-veine.

CHAP. IIII.

The description of the Gate-veine and his branches.

 Gaue you (because the order of dissection so required) a briefe compend of the distribution of the Gate-veine in the third chapter of the thirde Booke, reseruing there the more exact discourse vnto this place, which therefore wee will now attend as carefully as we may.

That which they call the Gate-veine [table 2.] some thinke is a propagation from the vmbilicall veine, to which as we sayde it is continued. It issueth out of the hollow part of the liuer, which part or rather the very ingresse of the vessell (betwixt the 2. small Eminencies of the liuer) *Hippocrates* and *Galen* and the whole family of the *Asclepiads* doe call *πύλας* the Gate. It is the greatest of all the veines next the hollow veine, and therefore *Galen* in the twentyeth chapter of his fourth Booke *De Vsu Partium* calleth it *μεγίστη*, or the great veine, the hollow veine hee calleth *μεγίστη*, or the greatest veine, but this most commonly he calls *the veine which is at the Gate*, because by the roots hereof, that is to say, the Meseraicke branches, the *Chylus* is suckt away from the stomacke and the guts, and through the trunk hereof as through an open gate is let into the liuer. Whereupon the *Meseraicks* are called *manus hepatis*, the hand of the liuer. The Physicians call it commonly *vena porta*, the gate-veine, the Arabians *venam lacteam*, or the milky veine, because it draweth the *Chylus* which is like vnto milke, but of the *lactes* there is another speculation.

For order sake we will diuide this Gate-veine into rootes, branches and the trunk it self. The roots are small and abundant, desseminated [tab. 2. char. 1, 2, 3, 4, 5] through the substance of the liuer from whence as from a principle of distribution (saith *Galen* in the fourth chapter of his Boode *de formatione fetus*, and in the third of the seuenth *de placitis*) and of Radication (saith *Hippocrates* in his Booke *De Alimento*) they doe arise. These small roots by degrees grow into greater, and those yet into greater, till all of them about the middle of the liuer on his hollow side neare vnto the backe are vnited, and make one notable trunk [tab. 2. B] which issueth out of the liuer. These rootes whilest they remaine in the liuer, are ioynd by inoculation into the middle of the rootes of the hollow veine as we haue shew- ed in the thirteenth chapter of the third Booke and the fourteenth table.

Ecce 3

The names of
the gate-veine
and the reason
thereof.

The diuision
of the gate
veine.

In

In dogs there are so many bowes of the gate-veine as there be lobes of the liuer, euery one of which is diuided into his owne lobe, and yet all of them meete into one common trunk. Notwithstanding they may be called Rootes and branches. Roots, because this veine is sayde to be the sprout of the Liuer, and because they leade blood vnto other parts. They may also bee called branches because the meseraicks (which *Galen* likening it to a tree, calleth the Rootes) when they haue suckt the Chylus doe send it vnto the Trunke, from whence by these branches it is distributed into the Liuer.

Sometimes from the rootes of the Gate-veine from the very top of the left part of the Liuer neare his Ligament, yssueth a braunch which is communicated to the Midriffe, and descending on the backside is ioyned vnder the *Pancreas* or Sweete-bread with other branches which arise out of the trunk of the gate-veine. Sometime also a few branches arising out of the same place doe attaine vnto the Spleene and are disseminated into his substance.

The trunk.

The Trunke [tab. 2. B] descending from the Liuer runneth a little obliquely downward vnder the Gutte called *Duodenum*, hauing gotten a firme seate about the Rackebones.

Where deu-
ided & why.

It maketh his distribution betwixt the Stomacke and the Guts as in the fittest place, because it is the middest of the organs of nourishment where it was fit that distribution should be, that the veines might be equally diuided amongst them. For if it had descended lower it had departed too farre from the Stomacke. If it had ascended higher, first it would haue beene too farre from the Guts; and againe, could not haue had so easie access vnto the stomacke, which sometimes strutteth with abundance, and againe falleth when it is empty. From this Trunke therefore diuers propagations are distributed in the lower belly into the Stomack, the Guts, the Kell and the Spleene.

The trunk
Cystica Gemela

The Trunke [tab. 2. B] before it is diuided parteth with two small branches from his foreside. The first are called *Cystica Gemella* the Twinne-veines of the Gall [tab. 2. C C] which yssuing fromward the left side of the trunk are reflected vward and toward the right side vnto the necke of the bladder of Gall and the body thereof, through which they are distributed in hayrie branches as are the small vessels through the white of the Eye.

Gastrica dextra

The second is called *Gastrica dextra* [tab. 2. D] the right stomacke veine. It ariseth much lower then the twins and rather from the right side of the Trunke on which side it passeth onely vnto the backparte of the stomack and the *Pylorus* or lower mouth thereof, and affordeth them small branches.

Ramus splen-
icus.

Afterward the Trunke inclining to the left hand is deuided into two notable bowes [tab. 2. E] the vpper or the left, and the lower or the right. The vpper [tab. 2. F] although it be altogether spent into the Stomacke and the Kell; yet from the vse it is called *Splenicus* or the Spleene-branch, because it draweth to it selfe out of the *Chylus* altered in the *Meseraicke* veines the thicke part of the iuyce before it bee gotten to the Liuer, and leadeh it to the Spleene as we haue sayde before in the History of the Spleene, wherefore also it is placed about the trunk of the Meseraicks. [tab. 2. G] The lower bow is called *Mesentericus* the mesentericall branch [tab. 2. G] because almost all of it is diuided into the Mesenteric.

Mesentericus.

The Splenicke branch being supported with the Membrane of the Kell and a glandulous body, runneth ouerthwart to the Spleene, and before it bee consumed therinto, there proceede branches out of it, some before some after the deuision. Before the diuision some yssue from the vpper part some from the lower. From the vpper part two veines spring.

Gastrica minor

The first is called *Gastrica minor* the lesser Stomacke veine, and [table 2. K] the left is deuided into the gibbous and backpart of the Stomacke with a few branches.

Gastrica maior

The second is called *Gastrica maior* [tab. 2. N] the great Stomacke veine, because it is the largest of all the veines that come vnto the Stomacke. It runneth obliquely vnder the stomacke to his vpper orifice or mouth, and is diuided therinto, sending out of the trunk three boughes; of which, one on either side is conuayed to the Stomacke, [tab. 2. O O] the middle runneth vward and compasseth the vpper mouth of the Stomacke like a crowne, and maketh that veine which thereupon they call *Coronaria stomackicam* the Crowne veine of the Stomacke, [tab. 2. Q] which in dogges is very conspicuous. From this veine some small ones are offered vward vnto the end of the Gullet, some downward to the Stomacke.

Coronaria
Stomackicam.

Sometimes also another branch arising from the other propagation runneth downward,

ward, and on the foreside passeth the *Pylorus* or lower mouth of the Stomacke with many Surcles. From the lower part yssue three branches.

The first is called *Epiplous dextra* [tab. 2, L] the *right Kell veine*. It is but a slender vessell, and deriueth his Surcles downeward to the right side of the lower membrane of the Kell, and to the Collicke Gut which is thereto annexed. *Epiplous dextra*

The second is called *Epiplous postica* [tab. 2, S] the *hinder Kell veine*. It is larger then the former and is deuided into 2. branches which are very much separated, out of which surcles doe runne downeward to the lower membrane of the Kell, (wherewith the Collicke Gut is tyed to the backe as it were with a Mesentery) and to some part also of the *Colon* it selfe. In Dogs there is no veine from the spleenicke branch vnto the Collicke Gut. *Epiplous postica*

The third called *Pancrea* [tab. 2, M] are many small and capillary veines which runne betwixt the two Kell veines as wel aboue as below, and are disseminated into the Sweetbread which is called *Pancreas* from whence they haue their name. *Pancrea*

When these branches are produced, the Splenicke [tab. 2, F] Trunke is cleft into an vpper and a lower branch, [tab. 2, T] and these into others.

From the vpper braunch doe arise sometimes three, sometimes more, sometimes one from the top of the branch neare the Spleene which they call *Vas breue* [tab. 2, the vpper Z] or *Vas venosum*, the *Short* or the *Venall vessell*, which is in some men greater, in some men lesser, and these latter doe easily indure hunger, the former with great difficulty. And hence it is that some men if they bee neuer so little a while without meate, or betweene their refectiōs they fall into a *Syncope* or swooning; by this braunch also come oftentimes blacke vomits. *Vas breue*

[Table 2. is the same with Table 3. lib. 3.]

These Veines being sustayned with the vpper membrane of the Kell, are inserted into the left side of the bottome of the Stomacke, and sometime higher that they might belch that naturall melancholly which could not bee changed into the Aliment of the Spleene, into the bottome of the stomacke; sometimes into his mouth (which *Vesalius* witnesseth that he hath seene) to stirre vp the drowsie appetite with his tartnesse, before the mouth of the Stomacke be corrugated for too much want; for that sowre thinges doe prouoke appetite we are taught by the sharpe Sallets that are vsed in the beginning of our Suppers. Beside, the adstriction or binding property of this humour strengtheth the mouth and helpeth the concoction of the body of the stomacke. Sometimes also from another propagation of this branch, veines are transmitted to the Stomacke, and these tye the Stomacke and the Spleene fast together.

From the lower branch of the Splenicke bough proceede two veines. The first is called *Epiplous sinistra* or the *Left Kell veine* [tab. 2, F] which in one or two surcles is distributed into the left part of the lower membrane of the *Omentum* or Kell, especially when the hinder Kell veine is narrow, wherefore this veine is not alwayes found. *Epiplous sinistra*

The second is called *Gastro-epiplous sinistra* [tab. 2, X] the left Stomacke and Kell veine. It is a notable braunch, and reflected to the right hand compasseth on that side the bottome of the Stomacke where the small branches of this veine are intangled with the slender surcles of the right, and touch either the other extremities. It affordeth also small branches, but very plentifull to the left side of the vpper membrane of the *Omentum*. *Gastro-epiplous sinistra*

The remaynder of both braunches being diuersly wouen together, are implanted in great abundance [tab. 2, Y Z] into the hollow and middle line of the Spleene, and are distributed through his whole body to purge the feculent iuyce, and to leade it to the spleen, and thus much of the left or vpper branch of the gate-veine.

From the lower and Right branch [tab. 2, G] which is also the largest, before it bee diuided, two veines do yssue.

The first is called *Gastro-epiplous dextra* [tab. 2, H] the *right Stomacke and Kell veine*. It yssueth from the side of the branch before it bee deuided into the mesentericall branches. Sometime it ariseth out of the Trunke it selfe, sometimes also but very rarely out of the left branch, and on the right side watereth the bottome of the stomacke both before and behind with many small surcles which insinuate themselues euen into his cavity. It cree- *Gastro-epiplous dextra*
peth also through the vpper membrane of the Kell, and at the middle of the stomacke it ioyneth his small surcles with the left *stomacke and kell veine*. [tab. 2, X] In Dogges some-
time

time it yssueth from the Gut-veine. Sometime it is wanting and then the left supplyeth the place of both.

Intestinalis.

The second is called *Intestinalis*, [tab. 2, 2] or the gut-veyne. It issueth sometimes out of the branch, sometimes out of the trunke at the middle of the *Duodenum* or the beginning of the *Ieiunum*, and runneth directly downward through their length, it disperseth certain small branches as fine as hayres through the vpper *Omentum* and through the *Pancreas*.

Afterward the whole branch [tab. 2, 6] where it ioyneth with the mesentery, departeth into three mesentericall branches, two on the right hand and two on the left.

*The mesentericall
veynes.*

The right mesentericall branch is double, [tab. 2, 6] and is implanted into the *Ieiunum*, the *Ileon*, the *Cacum*, and the right part of the Colon on the backe or hollow side, and being diuided into innumerable furcles, as the rootes of a Tree are diuided into slender strings (whereto also *Galen* compareth these) they make the meseraicke veines [tab. 2, dddd] which run obliquely betwixt the two membranes of the mesentery, and amongst which there are many small glandules placed to secure their passage and determine in the Guts; not into their cavity, for that is compassed about with a crust, but their little mouths do open into the coate of the gut, from whence they sucke the Chylus as the tendrils of a roote sucke the Iuice out of the earth. Wherefore in the guts called *Ieiunum* and *Ileon* they are more abundant, because they containe a greater quantity of Iuice then the great guts doe.

But they were not onely created to leade away this Iuice, but also to attract it and prepare it for the Liuer, after a manner, saith *Galen*, most like vnto it selfe, because their nature is alike, and they draw their first originall there-from; wherefore after they haue giuen vnto it the beginning or rude forme of blood, and out of them and from the blood the thicker part is drawne by the Spleene through the splenicke branch, [tab. 2, F] they leade it vnto the Liuer. For as Porters doe carry the dressed Corne into the Garner or common Store-house of a Citty where it is prepared for nourishment, so the meseraicke veines doe conuey the aliment laboured in the stomacke to the common place of the creatures concoction, that is, vnto the Liuer, not to poure it into his substance there to bee changed into blood, but to bee referued and laboured in the rootes of the Gate-veine, which are most what on the inside and hollow part of the Liuer, for vnto these rootes the Liuer giueth the power of sanguification as wee haue saide before in the tenth Chapter of the third Booke.

*The double
worke of the
meseraicks.*

Moreover, the same meseraicks by which the distribution is made of the Chylus from the guts to the Liuer, do also carry blood from the Liuer to the nourishment of the guts, yet not at the same time, but when they are empty and want nourishment, and if it happen that both workes concur together, which *Galen* yeeldeth to bee so in the nineteenth chapter of his fourth Booke *De Vsu Partium*, then according to the diuers nature, desire and strength of the drawing parts, the veines of the Liuer snatch the Chylus and the guts blood. For if you make Iron and Strawes into powder together and mingle them, heated Amber will draw away the strawes, and a Load-stone will draw away the Iron by reason of their diuers natures and diuers desires of attraction.

*Why there be
no values at
their ends.
Against Co-
lumbus.*

Now this double attraction could not be performed if the extreame orifice of the veines had values set vnder them as *Columbus* dreamed, but *Archangelus* refuteth him by many arguments, who saith, *Columbus* was deceiued by that crust which is ingendered of the excrements of the third concoction, and compasseth the guts no otherwise then the Scarfe-skinne closeth the extremities or ends of the cutany veines.

Beside, if there were any such values they would hinder the confluence of the humors from the whole body into the guttes, which is made eyther by the constraynt of Nature or of medicine, for saith *Galen De Natural: faculi*: the purgations of the whole body are made by the meseraick veynes, especially by the lower of them; and so much of the right mesentericke branch.

*The left me-
sentericke.*

The left mesentericke veyne [tab. 2, c] is disseminated into the left and middle part of the mesentery, and attaineth that Region of the collicke gut, [tab. 2, ee] which reacheth from the left side of the stomacke euen vnto the right gut.

*The internall
Hemrod-
veynes.*

From this descendeth a notable branch called *Hemorrhoidalis interna*, [table 2, gg] the inward emrod veyne (for the externall proceedeth from the hypogastricall branch of the hollow veyne) and it runneth by the end of the collicke gut vnder the right gut, [table 2, ff] whose extremity (which they call the Fundament) it compasseth about with a few small furcles, by which expurgation is made oftentimes in obstructions of the Spleene, of

foeculent

foeculent blood when it is too abundant, and that in many bodies at certaine and determinate times.

This veyne taketh his originall sometimes from the splenicke branch, from which also the Short or venall vessell issueth: and thus much concerning the branches of the Gate-veine.

Now the difference betwixt the Gate and the Hollow veines is, that the Gate-veine is more lax and soft, the Hollow-veine faster and harder, because the Gate-veine serues rather for attraction then for expulsion, for by it the spleene and the Liuer draw more then they doe expell.

The difference betwixt the Gate and the hollow veine.

On the contrary, the Gate-veine serueth rather for expulsion then for attraction, for by it the blood is expelled into the whole body although it is not a little assisted by the attraction of the members.

The vse of the Gate-veine is to distribute branches which may eyther serue for nourishment as those that leade blood into the naturall parts destituted and forsaken by the hollow veyne, or for the expurgation of some excrement as the splenicke branch which draweth vnto it selfe out of the trunk of the Gate-veine, before the Chylus attaine to the Liuer, a thicke and foeculent humor yet mingled with much laudable Iuice, and the *vas Breue* and the *Hemorrhoid-veine*. Other branches make for the distribution of the Chylus into the gate of the Liuer, in which also it receiueth an alteration and preparation of blood as the *meseraicks* and those veynes which we saide attained vnto the stomacke to draw a part of the Chylus euen from thence.

The vse of the gate-veine and of his branches.

Finally, others perfect the blood as those small veynes disseminated through the flesh of the Liuer, which we called the rootes of the Gate-veine.

Note moreouer that all the Gate-veine lyeth within the boly, neuer attaining vnto the skinne, and therefore his branches are not opened vnlesse haply about the Fundament, where they make the *Emrods*, (to which we doe more often apply *Horsse-leeches*) and in women at the necke of the wombe: and so much of the Gate-veine.

Note.

CHAP. V.

Of the descending trunk of the hollow veyne.

HE hollow veyne called *cava*, because of his large cavity, is by the Grecians called *κοιλία* and *μεγαλη* the greates veine, *Galen* sometimes, as in the fifth chapter of his fourth Booke *de usu partium* calleth it *μεισις*, the greatest veine. *Hippocrates* calleth it *επατινι* *Iecorariam* the liuer veine. This is the common mother of all the veines, except the vmbilicall and the gate veines. It hath one beginning of *Originall*, that is, the seede, for it is made at the same time with the other spermatieall parts which are made or generated together, though some of them be perfected and absolued before others.

The name of the hollow veyne.

His beginning

Another beginning it hath of *dispensation* and *radication*, and that is, the Liuer, and therefore it is said to yssue out of the gibbous part of the Liuer, where his substance is greater and thicker. For although the orifice of the hollow veine at the right ventricle of the heart bee much larger then his capacity in any other place, yet it doth not thence follow that it must arise from that right ventricle as *Aristotle* imagined, and after him *Vesalius*, rather to carpe at *Galen* then that he was mooued thereto by any waighty reason.

For the making and framing of this hollow veine, [table 3, figure 2, and 3. and table 4, shew it,] out of the vtmost circumference of the Liuer in the gibbous patt thereof, [table 2, fig. 2, C C] doe arise innumerable propagations of small veines [table 3, fig. 4, C C C. tab. 4, E E E E] which creeping by degrees toward the middle of the backside of the Liuer, [Table 4, C C] doe meete together, or vnite themselues into larger veines, and these againe into greater, till at length they all passe into the vpper part of the Liuer where it regardeth the right side of the backe into two very notable branches [ta. 3, fig. 3, M, N] the one disperfed into the right, the other into the left part of the Liuer: both which doe determine into one stalke, [table 3, fig. 2, F. fig. 4, A. tab. 4] which is called commonly *the trunk of the Hollow veine*. Wherefore this trunk applyeth it selfe, or inclineth from the right side of the Liuer to the backe side where it entreth, as it were into a *sinus* or cavity, and with a short passage groweth to his substance.

Whereof it is made.

This

This trunke is seated according to the length of the backe, and runs with a streight course through both bellies that so it might conuay vnto the whole length of the creatures blood

Table 3 is the same with Table 13 Lib. 3.

The inocula-
tions of the
gate and hol-
low veine.

(which is the common Aliment of all the parts) laboured in the Liuer in the roots [tab. 3, fig. 4, FF, tab. 4, KKKK] of the Gate-veine; which roots are implicated or intangled with the roots of the hollow veine, [tab. 3, fig. 4, CC, tab. 4, EEEE] dispersed confusedly through the flesh of the Liuer, touching one another in many places ouerthwart. [tab. 3, fig. 4, and tab. 4, shew this] Many roots also of the Gate-veine doe infix or fasten their extremities or terminations into the middle of the roots of the hollow veine, [tab. 3, fig. 4, GGGG, tab. 4, LLL] as on the contrary many ends of the roots of the hollow veine are fastened into the middle of the roores of the Gate-veine. By with Anastomoses or inoculations the blood is transmitted out of one veine into another, and so conueyed into the whole body. For the hollow veine is like a water-pipe full of blood which hath many riuersets some greater and some lesse issuing therefrom and distributed into all the parts. For Nature in this administration is not onely very prouident but also equall and indifferent, and therefore diuided this veine into many small parts that each member might haue his due proportion, that is to say, Aliment answerable to the substance that wasteth away. So hot and soft parts and those that are much exercised do suffer greate expence as the Lungs, and therefore their veine is very large: but colder and harder parts which are moderately exercised, are not so easily dissolved, as the bones which therefore haue very small & slender veines. Betwixt these are all the other parts thereof some haue more euacuation and some lesse, and therefore they want more or lesse nourishment.

Table 4 is the same with 14. Lib. 3. folio 132.

The hollow veine for order sake, and perspicuity we diuide into an vpper trunke [table 3. fig. 3, D, fig. 4, A, tab. 4, above A] and a lower, [tab. 3, fig. 2, at C, fig. 4, B, tab. 4, DD] the vpper piercing through the midriffe and climbing vpward distributeth very many branches into all the superior parts, of which we shall speake in the next chapter.

The descen-
ding trunke of
the hollow
veine.

The descending trunke [tab. 5, K] is lesser then that which ascendeth, because the vpper parts do require more blood; for that many parts in the lower belly contained receiue branches from the Gate-veine. It adhereth on the right hand to the bodies of the rackbones (for on the left side [tab. 5, L] the trunke of the greate Artery lyeth vpon them) and before it depart altogether from the Liuer, it disperseth certaine small branches into his substance which are not in al men of the same number. After it leaueth the liuer, it descendeth inclining something obliquely inward and disposeth from it selfe many branches, of which we will now intreat.

The lower trunke of the hollow veine [tab. 5, K] is diuided into a trunke and branches. From the trunke which runneth vnto the greate racke bone as Hippocrates calls it, or to the holy-bone, [tab. 5, n] commonly there issue foure veynes on each side.

Adiposa sinistra

The first is called *Adiposa sinistra* the left fatty veine. [tab. 5, g] It yssueth out of the left side of the trunke (although *Eustachius* be of the contrary minde) and presently being diuided sendeth one part to the fat, and to the vpper part of the vtter membrane of the kidneies for their nourishment as farre as to the middle of the kidneies. It sendeth also to the glandule which groweth about the kidney and to the midriffe it selfe [Tab. 5, A] which veines on the inside are very conspicuous and vnited with the veines of the midriffe.

The other part it distributeth into the lower part of the foresaide membrane.

Dextra.

The right branch ariseth rarely from the trunke, most what from the vpper part of the middle passage of the emulgent [ta. 5, f.] because the liuer which in this place is somewhat thicke [tab. 5, B C.] and stoppeth vp or intercepteth the way vnto the hollow vein, and therefore the left is for the most part about the right, yet it is distributed after the same manner the left was. And sometimes perforateth the glandule which groweth vpon the kidney with a surcle, which afterward is consumed into the vtter membrane of the kidney. It is very rare if both of them be produced from the Emulgent; more rarely doe the two veins yssue from the hollow veine about and neere the originall of the Emulgent. The vpper of them reacheth a small branch vnto the glandule, the lower is by another surcle ioyned to the branch which runneth from the seede veine of the same side.

Their origi-
nall diuers.

But if the left Emulgent be the higher, then sometime out of it the left fatty veine taketh his originall and the right from the trunke. So sometime on the right hand betwixt the fatty veine and the Emulgent there yssueth another veine which sprinklerh his branches vp into the midriffe, into the vpper part of the substance of the kidny and into the glandule of the same side.

After-

Afterward when the trunk of the hollow veine hath attained vnto the twelfth Rackbone of the Chest, and the first of the Loynes, then yssueth out of it the Emulgent.

The Emulgent which is the second of the foure wee before made mention of, is so called from his office or function. In like manner because it is inserted into the Kidney, it is called *Renalis* the Kidney-veine. The Emul-
gents.

[Table 5 is the same with Table 8. Lib. 3.]

It is the largest of all the veynes that yssue out of the Trunke [Table 9, d] for it is very thicke, yet short because they are as it were drawing stomackes and seruiceable to the Kidnies. In men and Apes they are on either side commonly but one, [Table 5, under d e] notwithstanding sometimes the right Emulgent is double, even from his originall as appeareth in the third Table of the fourth Booke, the first Figure, Charact. 1, and 2. Sometimes it is treble, rarely double on eyther side, and this variety is not onely found in diuers bodies, but also in one and the same, so as the vesselles of the right side differ much from those on the left.

Their originall is seldome directly opposite one vnto the other, least the function or office of one should bee interrupted. But the left is higher then the right in men but not in Dogs, because the left Kidney by reason of the smalnes of the Spleene, standeth higher, whereas the right is borne downe into a lower place by the magnitude of the Liuer. [Tab. 5] The left Emulgent also is larger then the right, because of the Spermaticeall veine which was to arise therefrom. Sometimes also from the lower part of the left Emulgent where it is implanted into the Kidney, there yssueth a small braunch which is transmitted vnto the lower part of the fat membrane, and is oftentimes ioyned with the Spermaticeall. The iourney of both the Emulgents is short and oblique, as appeareth in the third Table of the fourth booke; and about the middle and concauous Region of the Kidney before they get into his cavity, oftentimes in the very middle of their passage they are diuided into two or three, more seldome into foure or fve equall branches, which *Hippocrates* in his Booke *De Ossium Natura*, compares to Anchors fastened in the cavity of the Kidney. These branches of the Veine and the like of the Artery are implanted into deuided parts of the Kidneyes, not ascending, which is rare and then onely when it yssueth out of a lower place, but descending, and those branches are in great numbers subdiuided into the substance of the Kidneyes till they become as small as hayres. Their original

The vse of these Emulgents is to sucke and draw the whacy or serous moysture from the blood and to drayne it, they conuey also therewith a part of the blood it selfe for the nourishment of the kidneyes, but least this blood and whay should returne backe into the hollow veine, Nature hath placed valves or flood-gates, as it is also in the Veines of the Spleene. Their pro-
greffe and di-
uision.

The third veine that yssueth from the descending trunk, is called *Spermaticea* or *Seminalis* the Seed-veine. The Sperma-
tical veines.

The right of these [tab. 5, b] which is sometimes double, ariseth with a swelling original from the vpper side of the Trunke below the Emulgent rarely close to it, from which notwithstanding sometime it receiueh a small branch. The left ariseth [tab. 5, i] almost alwayes from the middest or the lower side. The reason whereof is, because if it should haue straddled ouer the great Artery, [tab. 5, L] so small a veyne would haue beene indangered by his pulsation: for eyther the continuall motion must haue broken it, or at least haue interrupted his office.

There is also sometime ioyned to this left Seed-veine, a branch yssuing from the trunk it selfe. The reason was, because the blood of the Emulgent being waterish, might be assisted by the purity of the blood of the hollow veyne.

These Seed-veynes descending obliquely, and passing through the productions of the *Peritonaeum* or Rimme of the belly about the share-bone, at the head of the Testicles are diuersly contorted and so attaine vnto that which they call *Varicosum corpus* or the *Boddenbody*, leading thither from the whole body the matter of the Seede, as we haue shewed before in the fourth booke.

But in women although their originall bee the same, yet they fall not out of the *Peritonaeum*, neyther doe they reach so farre as to the share-bones, but beeing supported with fat membranes are disseminated part of them vnto the Testicles, part vnto the bottome or soale of the wombe. More.

Moreover they affoord slender furcles to the Rimme of the belly and to the coats which inuest the Testicles.

Lumbaris.

The fourth vessell that departeth from the lower trunke, is called *Lumbaris* or the *Loynes-veyne*. They are two [tab. 5. m m m] or three arising from the lower part of the trunke, which is next vnto the spondels betweene foure rack-bones of the Loynes, and they passe through the holes made for the out-gate of the nerues in the sides of the racke-bones. Their vse is to water and nourish the spinall marrow.

Their vse.

Hippocrates

From these two veynes on each side one ascends into the braine at the side of the spinall marrow, which haply are those whereof *Hippocrates* maketh mention in his booke *de Genitura*, and it may bee they bring a portion of the matter of the seede downe from the braine, whereof *Aristotle* in his Problemes was so confident that he sayth it hath bene seene.

The Illiacke branch.

Muscula superior.

Sacra.

After the departure of these foure veynes the Trunke descending vnto the *holy-bone* [table 5. u] at the fourth racke-bone of the loynes inclineth vnder the great Artery, [Tab. 5. char. 14] that it might neyther bee hurt by the hardnesse of the bone, nor offended by the continuall motion of the Artery, and is diuided into two equall branches called *Rami Illiaci* or the *Illiack branches* which resemble the letter A or T inuerted, which runne obliquely about the haunch and share-bones vnto the Legge. Out of these on cyther side before the diuision doe yssue two veynes. The first is called *Muscula superior* [Tab. 5. n p n p] the *upper Muscle-veyne*, which ariseth euen in the very diuision from the vtter side of the branch; sometime it issueth out of the thumbe of the hollow veyne before the partition, and is transuersely or ouerthwart disseminated through the muscles of the Loynes of the *Abdomen* and through the Rimme of the belly; but their originall is not the same on both sides; and in dogs it is more manifest then in men. The second is called *Sacra*: [tab. 5. o o] or the *holy veyne*. It is but small sometimes single, sometimes double, and it is conueyed through the vpper and forward holes of the holy bone to nourish his marrow.

Afterward the Illiacke trunke on cyther side in his progresse [Table 5. r] is bifurcated into an vtter branch, [Table 5. s] and an inner, [table 5. p] and the latter is smaller then the former: from the inner branch proceed two veynes.

Muscula media

The first is called *Muscula media* [table 5. f f f] the *middle muscle veyne*. It is the outward propagation of the inner branch, and is deriued transuersely [Table 5. F] with many furcles into the muscles of the thigh, which occupy the vtter part of the hips, into the skin of the buttocks, and into the neighbour parts.

Hypogastrica.

The second is called *Hypogastrica*, [table 5. u u] the *veyne of the water-course*. It is the inner propagation of the interior branch. A notable veyne it is and sometimes double, and is diuided manifold, because it was to bee distributed for the nourishment of all the parts almost in the *Hypogastrium* or *Water-course*. One part of it runneth vnto the muscles of the right gut, and maketh the outward Hemrod veynes by which sometimes an abundance of thinne blood, falling hither out of the hollow veine, is auoyded without payne or torments of the belly; sometime also without paine in the Fundament, whereas the blood that issueth from the internall Hemrod made by the branch of the Gate-veine is alwayes painefull in the auoyding. Another part runneth out in men vnto the bladder with greate and large furcles, into the necke, I say, of the bladder and into the Yard. But in women it is but a little lengthened, and being sustained with a fat membrane it disperseth some furcles into the bladder, but many more into the lower part of the wombe and the necke thereof, by which oftentimes in women with child, and as some say in Virgins the courses are auoyded.

The outward Hemrod.

That which remaineth of his interior branch passeth on vnto the share-bone and assumeth vnto it selfe a little rillet from the externall branch, which together make a veyne [table 5. y] which perforateth the Rimme of the belly, and after also the tenth muscle of the thigh, and goeth through the hole of the share-bone.

From the outward.

From the vtter branch of the byfurcation of the Illiacke trunke, [tab. 5. p] which attaineth obliquely vnto the thigh, doe issue three veynes: two before it fall through the *Peritonaeum*, and one after.

Epigastrica.

The first is called *Epigastrica*. [tab. 5. character 1, and 2] It issueth from the vpper part of the vtter branch: sometimes also but more rarely from the Crurall, and offereth branches to the rim of the belly and to the muscles and skin of the *Abdomen*. The chiefe branch of this veyne piercing through the *Peritonaeum* runneth vpward on both sides vnder the right Muscle distributing diuers small branches into the transuers and oblique Muscles, and about the Nauill is ioyned by some furcles to the Mammary veyne that descendeth thither, by which *Bauhine* thinketh that notable consent is made betwixt the breast and the wombe, for those

Veynes

Veines haue their originall from the same deuision, from whence those other haue it which attaine vnto the wombe and the bosome thereof. For their endes or extremities ioine with the extremities of the *Mammary* Veines which descend through the capacity of the chest, and runne as farre as to the middle of the right Muscles, and in their descent do send branches through the distances of the gristles vnto the roots of the Pappes.

The second is called *Pudenda*. [Tab. 5. char. 15.] It ariseth from the inside of the outward bow after it hath gotten ouer the *Coxa*, and is fallen into the thigh, and hath perforated the *Peritoneum* or Rim of the belly. It reacheth ouerthwart to the middle of the share bone, and is distributed with a wonderfull increase, in men into the *Scrotum* or Cod, and into the skin of the yard, in women into the place of modesty, and the neighbour parts.

The third and last is called *muscula inferior* [Tab. 5. char. 13] the lower muscle veine. It issueth from the outside of the vter branch [Tab. 5. c.] and running through the ioynt of the hip, is disseminated into the muscles and skin of that place.

The rest of the propagations which issue from both the trunks [Tab. 5. c.] because they be no longer called *Iliacke* but *Cxprall* Veines, we will intermit till the tenth Chapter.

CHAP. VI.

Of the ascending Trunke of the hollow Veine.

E diuided the hollow Veyne into a descending and an ascending trunk; the descending we haue prosecuted in the former chapter, the ascending we take now for our taske.

The hollow veyne therefore after it hath passed through the neruous part of the midriffe, on his right side by a hole of purpose for it, paceth on through the Chest with his trunk vndiuided [Ta. 6. fig. 1. from A to D. Ta. 7. from a B to H.] euen to the *Inguinum*, that is, the hollownesse about the collar bone. It is a larger trunk then the descending, for it was to leade blood vnto more parts, and for more security is ioined to the midriffe, and to the right deafe eare of the heart. *Laurentius* saith it toucheth the *Mediastinum* likewise. In men there is question whether it do or no; *Vesalius* is against it, but in Dogges and Apes, said *Bauhine*, it doth without doubt: And least in the *Inguinum* it should be hurt by the hardnesse of the bone, and also that it might more safely be diuided into notable branches; there is a glandulous body couched vnder it called *Thymus*, in calues it is called the *Sweete-bread*. In Dogges and Apes (*Galen* saith also in men) a lobe of the Lungs is laide vnder it betweene the Purse of the heart and the midriffe, for their chests are longer then is a mans.

Before the diuision there issue out of the trunk foure branches.

The first is called *Phrenica* [Tab. 7. C.] or the veine of the midriffe, on either side one, which is disseminated through the midriffe in many furcles, and sendeth small branches to the *Pericardium* or purse of the heart, and to the *Mediastinum* or partition of the chest. The right of these issueth sometimes within the cavity of the chest; the left ariseth out of the trunk vnder the midriffe, wherewith also sometimes the Fatty Veyne called *Adiposa* is ioined. Presently the trunk of the hollow-veyne pacing on and perforating the *Pericardium*, and inclining a little to the left hand [Tab. 7. above B.] maketh a brode *sinus* or bosome before the heart ouer against the 8 rackbone of the chest or the top of the ninth; sometimes in the middle space which is betweene the seuenth and the eight racks. Where changing almost his substance and his roundnesse, it degenerateth in the right deafe eare, [Tab. 7. D.] of the heart; or if you will it is on euery side fastened to the right eare which it superficially embraceth. There it is infixed into the right vtricle of the heart, not penetrating very deepe, to the end it might poure blood into it as into a Cysterne.

Eustachius saith that there is a certain membrane set to the fore and inner side of the hollow veyne, which at the middle of the perforation determineth into many fibres, which being diuersly complicated doe make vp or fulfill the rest of the semi-circle, and without coniunction are spread ouer the whole perforation, that so the same membrane might be put forward and repelled backward by the matter that rusheth in or out. But this membrane sometime wanteth that texture or fibres, and resembleth the forme of the Mitted or horned Moone, as it is in the crowne veine. It is also sometime so small and narrow that (as if it were not at all) it cannot be descryed; which haply, saith *Bauhine*, is the reason that I haue not yet obserued it.

Ffff

The

Coronaria cordis
do.

The second branch which issueth from the trunk before the diuision is called *Coronaria Cordis* [Tab. 6. fig. 2. B, tab. 7. E.] the crowne veine of the heart, for, because it compasseth the basis of the heart, like a crowne or garland, the Grecians call it *σφαιριδια*. It sendeth many branches through the viter surface of the heart all ouer the bowell from the basis downeward vnto the *Muero* or poynt, especially through his left side; for, because the substance of the heart is there the thickest it stood in need of more plentifull Aliment, and because it required a thicke nourishment conuenable or agreeable to his substance, therefore it receiueth blood by this Veyne befor it get into the ventricle, where the blood becomming thinner is destined for the nourishment of the Lungs as is commonly conceiued.

His Value.

At the originall of this Crowne-veine there is placed a value or flood-gate like a halfe Moone, resembling that which in the heart of the Infant is set before the first *Anastomosis* or inoculation. This Veine keepeth the blood that is once allowed to the Surface of the heart that it flow not backe into the hollow Veyne, being shaken by the continuall motion of the heart. This *Crowne-veine* (saith *Galen*) is sometimes double; one on the back-side, another arising from the fore-side.

When the hollow Veyne hath allowed this garland to the heart it perforateth the purse thereof againe, and againe resumeth his round figure and becomming much lesser forsaketh the Rack-bones, because vpon them the Gullet and the rough artery doe leane, and runneth through the middest of the lungs where the right part is separated from the left vward vnto the *Iugulum* about the *Thymus*.

But that the Rack-bones and the spaces betwixt the ribs might not be destituted of veines; it yeildeth fourth a small trunk or notable Veine about the heart as it were in the very middest of the body.

The veyne
Azygos

This Veine which is the third before the diuision of the trunk is called *vena Azygos*, or *si-ne-pari*, the veyne without a companion, which we haue before called the *non-parill*. [Tab. 6. fig. 1 C. fig. 2 B fig. 4 B] The reason is because commonly in a man it is but one as also in a Dogge hauing no mate on the other side. It ariseth about the heart betwixt the fourth and fift Racke-bones of the Chest, out of the hinder [Tab. 6 fig. 4 A] and lower part of the hollow veyne as it regardeth the Rackes, but rather to the right hand then to the left.

Vesalius taketh *Galen* very deeply for inconstancy and irresolution concerning the originall of this veyne, to all whose objections *Bauhine* maketh answere, wherewith we could willingly make you acquainted, if we did not thinke that such altercations are fitter for other palats then we desire to be Cook vnto.

In Dogges after the originall it sinketh directly downeward to the sides of the Rackes, but in men it goeth not directly, but is reflected a little to the right hand and backward toward the spine about the right trunk of the rough Artery. When it hath touched the rootes of the Racke-bones it is lifted vp, and passing on to the midst of them it descendeth downeward, so that about the eight or ninth Racke-bone of the Chest it is in the very middest, and runneth downeward vnder the Artery, which beareth vpon it as farre as to the end of the Chest (but deuided before) and with the great Artery peirceth thorough the Midriffe. In most creatures (in which I would haue young men exercise themselves) it taketh his originall from the left side of the hollow veine, and descendeth through the cauity of the Chest on the left side; which indeed in Sheep is alwayes true, but in those creatures which chew the Cud in whome it is double, (which in men is very rare, vnlesse you will say it may be so in those that be Ambidexters, that is, can vse both hands alike,) the right occupyeth the roots of the ribs on the right side, and the left the roots of the ribbes on the left side.

The veyne described by *Falopius*

In like manner sometimes as we are taught by *Falopius* [ta. 8. i.] there is found in men on the left side another veyne [Tab. 8. i.] which performeth the office of the *Azygos*, and then the other on the right side paceth neare the roots of the ribs, but ariseth not about the middest of the racke-bones.

[Table 7, is the same with Table 6, lib. 7.]

This last Veyne taketh his originall from the *Subclavian* branch, and affoordeth small furcles to some of the spaces betwixt the ribs, and sometimes at the fift rib is vnited with the branch which from the Trunk of the *non-parill* is sent ouerthwart [Tab. 8. EE] to the left side ouer against the fift Racke of the Chest, from which also a small branch ariseth vward. Sometimes it ariseth not from the *Subclavian* branch, but out of the Trunk of the hollow

veynes

Veine before his deuision against the third Racke-bone of the Chest, and sendeth small branches vpward to the two first spaces betwixt the ribs. His other surcles it affoordeth to the lower spaces of his owne side, as farre as to the fixt Rack-bone, whither when it hath attayned, it is ioyned with the foresaide transuerse branch, from which surcles are sprinkled into the rest of the distances betwixt the ribs.

Commonly from the trunk of the Veine *Azygos* [Ta. 6. fig. 4. B tab. 7. FF. ta. 8. d] which is seated as it were in the middle of the body; out of the back-ward Region (I say) thereof, as well on the right hand as on the left (but from the right especially) branches are distributed to the distances of the ten lower ribs, [Ta. 6. fig. 4.] sometimes but rarely to all the distances of the ribs, and those branches are called *Intercostrales* [tab. 7. GG] passing along in the distances of the true ribs as farre as to their gristles: but in the distances of the bastard ribs they run out to the muscles of the *Abdomen*.

The Intercostrall veins.

It distributeth also an abundance of small branches to the Gullet; sometimes and that not seldome, when it ariseth from against the fourth racke-bone of the Chest, it sendeth a branch vpward, [tab. 8. at the upper d] from which surcles are deriued with a wandring passage to the foure vpper ribs.

The propagations of the *Intercostrall* Veines doe fall also out of the Chest, [ta. 8. XXX] and on both sides in some places are vnited by inoculation [Tab. 8. YYY] with the surcles of the lower *Chest-veine*. Whence it is that in the *Pleurisie* we do not alwaies vse, as *Vesal. us*, to open the Veine on the right side, but finde it profitable to Phlebotomize the inner Veyne of the cubite on the same side the paine is. For because of this vnion, reuulsion is made more commodiously and more easily.

When the Trunke of the Veine *Azygos* hath attayned to the eight and ninth ribbe, sometimes to the tenth saith *Hippocrates* in his booke *de natura ossium*, it is deuided about the Spine into two boughes: a right and left, which *Falopius* and *Eustachius* did first obserue, [Ta. 6. 00] both which doe creepe downward and passe through vnder the diuision of the Midriff.

2 boughes of the Azygos

The one of these, and for the most part the greater, on the right hand determineth most what with one branch into the back-side of the hollow Veyne, neare the beginning of the Emulgent. Sometimes into the middle of the Emulgent, [Tab. 8. EF] where it bringeth forth the Seede-veine. Sometimes againe it is reflected in the cauity of the backe, and vnited againe with a small branch yssuing from the Emulgent. Sometimes also this left branch is deuided into 2. branches, one of which runneth vpward [tab. 6. fi. 4. ED] the other downward by the roots of the ribs, and affoordeth branch is to the distances betwixt them.

The left.

The right bough approaching to the hollow Veyne, is sometime ioyned thereto about the Emulgent, sometimes it is ioyned to the Emulgent it selfe, but that rarely: Sometime to the first Veyne of the Loynes, but most commonly it is implanted into the last [Tab. 8. *] of the Loynes. We also finde in some bodyes a small branch running obliquely by the Racke-bones, and penetrating or making way into their cauity. Whereupon we conclude, that in the beginning of a *Pleurisie* the Veine of the Hamme or that of the Foote called *Saphena* may be opened.

The right.

Nota.

Hence also it is that many *Pleuriticke* Patients are critically purged, Nature auoyding an abundant quantity of Pus and Matter by the vrine. Moreover it hath beene obserued that in those which we call *Empyici*, the Matter hath beene conuayed through the venall Artery of the Lungs into the left ventricle of the Heart, thence into the great Artery, and so into the Kidneyes, and continually auoyded by the vrine. Wherefore this distribution of the Veyne *Azygos* and his vnion sheweth how the Chest may commodiously be purged by the vrine. The Rack-bones also along which it runneth and the *Mediastinum* receiue surcles herefrom.

How the chest is purged by vrine.

Now whereas *Amotus Lusitanus* in his Centuries, and with him *Hollerius* affirme that the beginning of this Veyne hath Membranes or Flood-gates, such as are found in the orifices of the vesselles of the heart which admitte the ingresse of the bloud out of the hollow Veyne into this *Azygos* but hinder the egress; they are much deceived saith *Bauhine*: for I could neuer obserue any such eyther in men or in brute beasts. Adde hereunto that if you open this *non parill* below, presse it out and put a bugle thereinto, when you blow the bugle, not onely this Veyne but the hollow Veyne also will swell. Their opinion therefore falleth to the ground, who think that when a Veine is opened in the arme, though the hollow Veyne be emptyed, yet there is no depletion made out of the *Azygos*, because those values do hinder the egress of the blood into the hollow Veyne.

No valves in the Azygos.

Ffff

The

*Intercoſtalis
ſuperior.*

The fourth veine that ariſeth out of the trunke before the diuiſion is called *Intercoſtalis ſuperior*, the vpper Intercoſtall veine. [Tab. 6, fig. 1 F. Tab. 7, K] There is one of them on each ſide ariſing from the ſubclavian branch neare the beginning of the Iugular veine. [Tab. 7. S T.]

Sometime the right veine ariſeth from the trunke, and the left from the branch. It is reflected vnder the Artery of the arme, and for the moſt part (eſpecially on the right ſide) is diuided into two branches which are diſtributed ſometimes into two, ſometimes into three diſtances of the vpper ribs which are ioyned with the mammary branches [Tab. 7, L L] which creepe through the griſtles. This veine is then wanting when the *Azygos* affoordeth branches vnto all the diſtances of the ribs.

In like manner from all the Intercoſtall veines there iſſue certaine ſmall ſurcles which inſinuate themſelues into thoſe holes of the rack-bones, out of which the nerues do iſſue for the nourishment of the bones and the ſpinall marrow.

*The diuiſion
of the trunke.*

The trunke of the hollow veine being deliuered of theſe veſſels [tab. 7, H] aſcendeth directly vnder the breſt bone aboue the great artery at the Iugulum, where it is ſupported by the *Mediaſtinum* and the *Thymus*, and is diuided into two notable bowes, [Tab. 7, II. tab. 8, CC] one of which runneth to the right ſide, the other to the left, and as long as it remaineth in the Cheſt it is called *Subclavius*, *Columbus* and *Falopius* call it *Axillaris*.

Table 8 is the ſame with Table 7, Lib. 6.

*The ſubclavian
branches.
Mammaria
deſcendens.*

From each ſubclavian branch ſome veins iſſue from the lower part, ſome from the vpper. From below before the ſubclavian is diuided do ariſe foure veines or branches. The firſt is called *Mammaria deſcendens* [tab. 6, fig. 1, EE. tab. 7, LL. tab. 8, I] The deſcending mammary veine whoſe originall is diuers, for ſometime it ariſeth from the fore and middle part of the byfurcation, ſometime from the roote of the ſubclavian, ſometime the left ariſeth from the ſubclavian and the right from the byfurcation. Sometime there is but one which ariſeth out of the middle of the trunke of the hollow veine before the diuiſion, which when it hath attained vnto the breſt bone is diuided into a right and a left.

This mammary veine inclining forward and running vnder the breſt-bone, getteth out againe at the ſides of the griſtle, which we called the breſt-blade, and creepeth along the vpper part of the *Abdomen*, allowing ſurcles thereto, and in his deſcent affoordeth ſmall branches to all the griſtly diſtances of the ribs (for the bony diſtances are ſupplied by the *Azygos*) which are ioyned with the extremities or end of all the intercoſtall veines. A part of this mammary veine getteth out of the Cheſt to the muſcles that lye therevpon and when it hath diſtributed his ſurcles part vnto the paps, part vnto the reſt of the breſt, it is led downward vnder the right muſcles of the *Abdomen*, to which his branches are tyed and the extremities of his diuiſions do vnite [Tab. 7, M] with a ſmall Epigaſtricke Veine [tab. 7, e] which aſcends vpward. Other ſmall veſſels alſo runne vnder the ſkin to the *Hypochondria*, which veſſels are made partly of the commixtion of the Intercoſtall Veines with the mammary, partly of thoſe which nourish the Intercoſtall muſcles, with which alſo others are vnited which aſcend from the groynepward.

Mediaſtina.

The ſecond Veyne iſſuing from the ſubclavian before his diuiſion is called *Mediaſtina* [Tab. 2, lib. 6, Q] which ariſeth from the trunke, ſometimes from the left ſubclavian againſt the internall Iugular. Sometime it is but one veyne and that large derined downward aboue the hollow part of the Lungs and aboue the purſle of the heart, and is diſſeminated thorow the *Thymus* and the *Mediaſtinum*. Sometime they are two ſurcles which runne through the *Mediaſtinum*, one of which is ioyned with the aſcending Veines of the Midriffe, the other paſſing downward with the left nerue of the midriffe, is inſerted into his fleſhy ſubſtance, and this inſertion is better perceiued in young bodyes then in Auncient.

Cervicalis.

The third Veyne is called *Cervicalis*, [Tab. 6, OO. Tab. 7, NN] or the necke-veine. It is not very large, and runneth obliquely vpward and backward by the laterall proceſſes of the racke-bones of the necke, and paſſeth the holes made in them, affording ſurcles to the muſcles that lye next vpon the bones. It ſendeth alſo others through the holes made for the nerues to nourish the marrow of the necke, and there is conſumed. *Laurentius* thinketh it aſcendeth vnto the braine.

*Muſcula in-
ferior.*

The fourth is called *Muſcula inferior*, [tab. 7, O] the lower Muſcle-veine which ſome

Sometime issueth out of the externall Iugular, and is distributed through the vpper muscles of the brest and the lower of the necke. And these foure issue from the *subclavian* branch before it get out of the cavity of the Chest. Afterwards when it is gotten out of the Chest, [tab. 8. P.] it changeth his name and is called *Axillaris*. From the axillary veyne before it be divided, two veines are propagated.

The first is called *Scapularis interna* [tab. 7. Q.] the inner blade veine and is distributed through the muscles on the blade, and those that are neare them, where also those small branches doe appeare which passe through the glandules that are vnder the arme pits. *Scapularis interna.*

The second is called *Scapularis externa* [tab. 7. d.] the vpper blade veine, because it passeth into his gibbous and vpper part: the other part of it runneth betweene the flesh and the skinn. *Scapularis externa.*

Afterward the axillary branch is divided into two veines, [tab. 6. H I. tab. 7. a m.] one superior which is called *Cephalica*, [tab. 7. a. tab. q.] or the head veine, the other inferior [tab. 7. m. tab. 8. r.] called *Basilica*, of both which we shall speake more in the ninth Chapter. In the meane time you shall know that from the trunk of the *Basilica*, two veines doe issue. *Cephalica Basilica.*

The first is called *Thoracica superior* [tab. 7. P P. tab. 8. f.] the vpper chest veine, which applyeth it selfe to the brest, and is distributed into the skin and the muscles which couer the brest: in women it yeeldeth a great number of veines vnto the dugges. *Thoracica superior.*

The second is called *Thoracica inferior* [tab. 7. R R. tab. 8. t t.] the lower chest veine. It runneth all along the side of the chest and his branches are inoculated [tab. 8. y y.] with the branches of the veine *Azygos* [tab. 8. X X.] which issue out of the chest (wherefore wee may draw blood in a pleurisie out of the axillary veine of the pained side) and are distributed through the broad muscle of the arme. This lower chest veine ariseth sometimes out of the vpper, sometime out of the *Basilica*. And thus much for the veines arising from the lower part of the *subclavian* branch. *Thoracica inferior.*

From the vpper part of the *subclavian* branch arise three veines on each side. The vpper muscle veine and the two Iugulars, one externall, another internall, which ascend vnto the sides of the necke, and at whose orifices there are two valves which hinder the relapse of the blood, for otherwise the vpper parts should haue beene defrauded of Aliment.

The first I said was called *Muscula superior*, [tab. 7. b b. tab. 8. o.] the vpper muscle veine. It ariseth neare the externall Iugular [tab. 8. n.] and is diuersly dispersed into the skin and muscles that are on the backside of the necke. *Muscula superior.*

The second is called *Iugularis externa* [tab. 6. fig. 1. II. tab. 7. T T. tab. 8. M] the externall Iugular veine. It is one commonly on each side, yet sometimes double from the originall, sometime it groweth double in the middest of his passage. It runneth vpward vnder the skin affoording furcles to all the outward parts of the necke, of the head and of the face, on his owne side, and for the most part vnder the roote of the eare it is divided into an vpper and inner branch, as we shall say in the next Chapter when we speake of the Veines of the face. *Iugularis externa.*

The third and last is called *Iugularis interna* [tab. 6. fig. 1. K K. tab. 7. T T. tab. 8. m.] the internall Iugular Veine. In man because of the abundance of his braine it is greater then the externall, but in dogs lesse. At the side of the rough Artery it sendeth small furcles thereto and to the neighbour membraness, thence it climeth vnto the chops, and hard at the head is byfurcated or divided, and there we leaue it. *Iugularis interna.*

CHAP. VII.

Of the veines of the Face, the Eyes, the Nose, the Teeth, and the Throttle.

WE said euen now that the externall Iugular Veine was vnder the roote of the Eare divided into an vpper [tab. 7. y.] and an inner branch. [x] The inner runneth to the muscles of the mouth, the chops, and the bone *Hyois*. In the mouth it maketh those two notable Veines vnder the tongue [tab. 7. t] which from their colour rather then from their figure are called *Ranina* the Frogge-Veines, which Veines in diseases of the mouth, the heate of the throat and the squinsie are opened for deriuation after euacuation and reuulsion made by the Veine of the Arme. From it also are many furcles deliuered ouer to the Larynx or Throttle, to the glandules there-to growing and to all the parts of the chops for their nourishment. Afterward appoaching

ching to the skull it entreteth thereinto through a hole of the temple bone neare the mammillary proceffe and so goeth into the *sinus* of the *dura mater*. There also passeth a vein on the outside of the orbe of the eye, by the hole of the wedge bone which is likewise disseminated into the *dura mater*.

The vter branch.

Vena Frontis.

The vter branch creeping vp the skin, and the muscles of the head vnder the care is supported with Glandules, and diuided into two progagations. One of which runneth to the forehead of the face [tab. 7. 2.] and is allowed to the nose and the puffed of the cheek, and in the middle of the forehead it is ioyned with the branch of the other side, and maketh the veine of the forehead [tab. 7. a.] which in some cases is wont to be opened. Another progagation thereof runneth by the side of the head, and sprinkleth veines partly to the temples [tab. 7. a.] partly to the Nowle of the head. [tab. 7. *] The branches of this exterior veine are diuersly mixed in the face and the sides of the head: from which some small furcles are distributed into the sutures of the scull and the small holes or perforations thereof. And so much of the externall Jugular, now we come vnto the internall, where we left it at his bifurcation hard at the Head, in the end of the chapter going before.

CHAP. VIII.

Of the Veynes disseminated through the Braine.

The inner Jugular.

The first of the Braine.

The second

The third,

The 4. and 5.

Vesalins and Platerus adde a sixt.

Falopius.

THE inner Jugular veine when it attaineth on the backside to the Basis of the Scull is diuided into two branches, whereof the one being the larger is carried backward, the other which is the smaller is carried forward.

The first is led along the basis of the scull with the lesser branch of the sleepey artery, and when it hath afforded furcles to the Muscles which lie vnder the gullet, it getteth into the scull and so into the *sinus* of the *dura mater*, through the first hole of the Nowle-bone which was prepared for the first paire of sinewes.

The second which leaueth the sleepey Artery, runneth forward after it hath sent a furcle to the organ of Hearing through the fourth hole of the Temple bone, it entreteth into the scull by the seuenth hole of the Wedge-bone and walketh through the basis and the sides of the *dura mater* or thicke membrane leading them Aliment, because they are far distant from the third *sinus*: from these also do yssue some furcles which creepe vp the *Pia Mater*.

Bauhine accounteth the third veine of the braine to be the inner branch of the externall Jugular which diuideth it selfe into three furcles, and entereth into the scull by the hole of the temple-bone which is neere the Mammillary proceffe, of which we spake in the former chapter.

The fourth and the fift Veynes of the Braine he saith do proceed from the same interior branch of the externall iugular, the fourth entreteth into the scull out of the orb of the eye by the second hole of the Wedge-bone, the fift out of the capacity of the Nofethrils by the hole of the *sciue* or spongy bone. The vse of these two latter Veins is to nourish the fore part of the Braine, because vnto it the third *sinus* doth not reach but determineth neere the distinction of the Mammillary processe. These Veynes also because they are small haue no Arteries ioyned with them, yet there is a furcle sent thither from the first artery of the Braine.

Beside these five Veines Vesalins and Platerus affirme, that there is another which they call The first Veine of the Braine, which is the end of the Neck-bone. For when the Neck-veine cometh vnto the top of the necke that which remaineth of it, together with the Artery his companion, passeth through the third hole of the Nowle-bone, which postern was particularly made for this priuat vse: or if that be wanting through the second, which was made for the seuenth paire of sinewes, and determineth on both sides into the *sinus* of the *dura mater*.

Bauhine ingenuously confesseth, that he could neuer finde this passage and yet makes mention of it, because other men should not want occasion to enquire after it. For saith he, the Necke-veine is partly consumed or taken vp in the perforations of the rackbones of the necke, yet so that it toucheth not the first racke: partly his branches are disseminated into the backside of the neck, having first transmitted some vnto the Muscles in that place (as we are taught by Falopius) which Veynes are vnited together among themselves, and together also with others which are sent out of the *sinus* of the *dura mater*, through the large hole of the scull, for there are many veines which from the *dura Meninx* are propagated to the outside of the head

head through the Sutures comming from without : which saith *Falopius* gave occasion to some to thinke that they were outward veines which went in through the holes of the Scull into the *sinus* of the *dura mater*, whereas they are rather internal Veines which get out at those holes and are ioyned with the externall.

The vse of the veines of the Braine which are in innumerable multitudes disseminated into both parts thereof and into his marrow (and although some of them be so smal, that he which is not quick-sighted cannot perceine them, some of them are conspicuous enough) the vse I say of them all is three-fold. The first to minister vnto the Braine his Aliment, that is Blood, & that in great aboundance, because the quantity of the Braine is great. And truly that there is abundance of Blood in the head doth easily appeare in dissections after inflammations of the Braine.

The vse of
the Veines of
the Braine.

Their second vse is to transmit vnto the Braine naturall spirit from the Liuer for the nourishment of the Naturall spirit which is in the Braine.

The third, that together with the naturall spirit the naturall soule, which is called also *Vegetativa* or the growing faculty, might be conducted into the braine; for because in the braine there is a faculty to draw, retaine, concoct and expell the Aliment or superfluities thereof, it is very necessary that it also should haue in it the naturall Soule either of it selfe or deriued from other where. But because the seat of the naturall soule is concluded to be in the Liuer, it must needs follow, that it can no otherwise be conueyed to the braine but through the veines.

Archangelus

Archangelus addeth a fourth vse of these veines of the Braine, and that is, that by the veines as also by the Arteries, the seede might be made fruitfull. For *Hippocrates* saith in his booke *de Genitura*, that those are barren and vnfruitfull whose Veines behind their eares are cut or diuided, and his reason was because he thought that a great part of the seed fell neere the eares from the head into the spinall marrow. But if the passage be stopped vp by a Cicatrice growing vpon the wound of the vessell, then shall the current of the seede be interrupted.

Concerning which difficulty and the interpretation of *Hippocrates* meaning, we haue disputed at large in the fourth question of the fift booke, and therefore we will not trouble the reader heere with fruitlesse repetition, but send him thither if he desire to be further satisfied concerning that matter.

Beside the veines and other vessells of the brain. It hath a priuate vessell which is called the *sinus* of the *dura mater*; full of blood, but beating like an Arterie, into which three veines and two Arteries do powre their matter, which sinus according to the diuers course and inclination thereof is diuided into foure: greater indeed then the veines that attaine vnto the scull and more capacious, not round but triangular. The whole sinus consisteth of three ribbes all of equall longitude, and of the fourth part of a circle incurued. From these do arise branches or passages like vnto veines, and doe distribute blood as well Vitall as naturall into the substance of the braine. But because we haue entreated sufficiently hereof in our chapter of the membranes of the braine which is the seauenth of the seuenth Booke, where also we haue exhibited the figure thereof vnto you, we will heere put an end to the veines of the Braine, and passe on vnto the veines of the Arme.

The sinus of
the Braine.

CHAP. IX.

Of the Veines of the whole Hand in the large Acceptation.

E said before that the Trunke of the Hollow-veine vnder the breast-bone at the very *Iugulum* or sticking-place [Ta. 9. fig. 1 H] is diuided into two notable branches, [II] one of which runneth to the right hand, the other vnto the left, and as long as it is within the Chest it is called *Subclanius*, but after it is gotten out because it runneth to the arme-holes it changeth his name and is called *Axillaris*, from which diuers Veines do yssue, of which we haue spoken before: but the Axillary veine departeth into two branches, one vpper which is called *Cephalica* [a] or the Head-veine, the other lower which is called *Basilica*, [m] so that both of them haue the same Originall, and of both of them will we intreat in this chapter.

The trunke of
the hollow
veine.

The *Cephalica* or head-veine [a] is the vpper branch of the *Axillary*, but it issueth from the externall *Iugular* veine. It is called *Cephalica* because it is wont to be diuided or opened in diseases of the head. It is also called *Humeralis* or the veine of the arme, because by the arme

Cephalica

it descendeth vnto the hand. It is also called the *Outward* veine, because it runneth on the outside of the Cubit. For passing along by the top of the arme it runneth vnto the cubit and the hand betwixt the fleshy membrane and the coate of the muscles, and before it hide it selfe vnder the arme it sendeth out sometimes one, sometimes two little branches [dd] which are distributed through the muscle of the arme called *Deltoides* and the skinne wherewith it is covered: then it passeth to the outside of the Cubit in which very place some make the beginning of the *Cephalica* veine, and call that part about it the *Humerary* veine. There also it is very conspicuous euen without sectiō, except the man be either too fat or haue smal veines. But in the descent, there issue from it small veines as far as to the ioynt of the Cubit or the elbow, part directly, part creeping obliquely into the muscles of the arme and into the outside of the skin, so that some-times it seemeth to vnite it selfe [f] with the branch of the *Basilica*, which is distributed lifewise in the skin.

The diuision
of the *Cepha-*
lica.

Sometimes a branch is sent to the inner muscles of the Cubit, which branch in men is most commonly wanting: but when it cometh vnto the ioynt or bow of the Cubit, [f] it is diuided neare the externall protuberation of the arme into an inner and an out-ward branch.

The inner
branch.

The inner at [b] being led along vnto the middest of the bent of the Cubit vnder the skin ioyneeth or vnith it selfe with a branch of the *Basilica* at [t] and so maketh that veine which is called *Mediana* or the middle veine [a]. But sometimes this branch is scarce conspicuous, whereas the veine opposite proceeding from the *Basilica* is very manifest, and sometimes it is quite contrary.

Mediana.

The veine called *Mediana* [a] hath his name from his situation, and it is also called *Communis* or the *Common* veine, because it is formed of branches of the *Cephalica* and *Basilica* running both into one. [b] This coniunction is made commonly in the very bought of the arme, sometimes much lower not far from the middle of the length of the Cubit, and by *Anicen* is called *The blacke-veine*. It runneth obliquely downward through the middle Region of the arme, & about the *wand* sprinkleth surcles on either hand, sometimes also it assumeth others frō those which runne through the inside of the Cubit. But about the *Radius* or *wand* [below p] it is diuided into two [z] branches. The vter [y] sendeth a surcle marked with [d] to the inside of the wrest toward the Thumbs, and is mingled with others. [q z] The remainder runneth out toward the Region of the thumbe and forefinger which some call *Sallustella*; but commonly the Chyrurgions call it *Cephalica*, others *ocularia*. The inner branch [e] is spent in many surcles betweene the fore and middle fingers, and some deale into the ring finger.

Some thinke this to be that which *Anicen* calleth *Syele*. But the truth is, that the distribution of the veines which run vnder the skin of the hand is so diuers, yea in the Cubit it selfe, that the same mans right arme duth scarce agree with his left, but two men alike you shall not find among a great many, and therefore their deliniation is harder to score out.

The vter
branch.
Funis Brachij.

The vter branch of the *Cephalica* by *Anicen* called *Funis Brachij*, the Chord of the arme [I] goeth obliquely by the *Wand* into the length of the Cubit on the outside, sprinkling small veines as he goeth [K] into the skin. But when it hath attained vnto the middle of the wrest on the inside neere to the *vlna* or *Ell* [l] there is ioyned to it a small branch of the *Basilica* [X] wherewith being increased it climbeth ouer the out side of the wrest, and with a small branch entangleth that part of the hand which lieth before the ring and the little fingers, and maketh that veine with the Arabians call *Syele*, we commonly *Sallustella*, which in the backe of the hand appeareth before the fingers. The section of this veine in the left hand is held by the Arabians and by many other Practitioners in physicke to be of great auaille in melancholy diseases. Sometime this branch of the *Cephalica* is wanting & his stead is supplied by a branch of the *Basilica* [x] which runneth throughout the length of the Ell, sometime it is supplied by branches issuing from the *Mediana* into the skin.

Sallustella.

Basilica.

The lower branch of the Axillary veine is called *Basilica*. [Ta. 9. mm] It is greater and larger then the *Cephalica*, and deuided into more surcles, many call it *Axillaris*, the veine of the Arme-hole, some the *inner veine of the cubit*, because it descendeth by the inside of the cubit.

Hepatica.

Lienaris.

Amongst practitioners it changeth his name in respect of the Arme, for in the right arme it is called *Hepatica* or the *Liuier-veine*, because it is opened in diseases of the *Liuier*. In the left Arme it is called *Lienaris* or the *spleene-veine*, because it is opened in diseases of the *Spleene*. It passeth along the inside of the arme among the muscles which compasse the bone, and at the Arme pit is entertained by many Glandules, where also it is diuided into diuers propagations:

f. A threefold diuision of the arme. *Cephalica* running c. l. The third branch l. m. propagations: the chest, and of. veine, runneth n. chest, and where. speake plainer, f. four on each f. Hence any n. ther the veine. It sendeth.

Table 9. Figure 1. sheweth the Cephalica and Basilica Veines & their branches.

TABVLA. IX.

H The by-partition of the hollow veine vnder the breast bone neere the *Iugulum*.

I, The subclavian veine, on either hand, about the vtter and inner *Iugular* veine, with that which is called *Cervicalis* or the Necke-veine.

K, The vpper intercostall veine.

LL, The Mammary veine.

O, *Muscula*, which goeth to the lower muscles of the necke and the vpper of the Chest.

P, A veine which reacheth vnto the muscles that lie vpon the Chest vnto the skin of that place, and vnto the dugges.

Q, A veine that goeth vnto the backe side of the chest to the hollow part of the blade and to the neighbour muscles.

* Small veines to the glandules vnder the Arme-pits.

R, A branch distributed along the sides of the Chest, especially into the broad muscle.

a, The Humerary veine called *Cephalica*.

b, A branch vnto the backward muscles of the necke.

dd, Branches from the *Cephalica* to the muscle that lifteth vp the arme.

ee, Small veines out of the *Cephalica* dispersed through the skin of the arme, & the muscles that lead the arme backward.

f, A threefold diuision of the *Cephalica*. g, The first branch to the muscles arising out of the externall protuberation of the arme. h, A branch of the *Cephalica* which helpeth the *Median* veine. i, The third branch of the *Cephalica* running obliquely about the *Wand*. k, Surcles that runne vnto the skinne from this third branch. l, The third branch at the wrist ioyned with the branch of the *Basilica* noted with x, their coniunction is at l. m, The veine called *Basilica*. n, o, A branch running by the heads of the muscles of the cubite at n, also branches to the muscles themselves at o. p, A notable branch of the *Basilica* carried obliquely and accompanied with the fourth nerue. q, The diuision of the *Basilica* into two branches, and that which is noted with q, is alwayes accompanied with an artery. r, The deepe branch of the *Basilica* bypartited or diuided into two. s, The other branch that goeth to the flesh and the skinne. t, A branch of this to the skinne of the arme. u, That branch of the *Basilica* which with the *Cephalica* branch b maketh the *Median* veine at cc. v, A branch of the *Basilica* going to the inner head of the arme. xx, A branch out of the former going to the wrist, and toward the little finger ioyning it selfe with the *Cephalica*. y, A branch nourishing the skinne at the outside of the cubit. zz, The vpper z sheweth a propagation out of the branch of the *Basilica* marked with t, the lower z another out of the *Basilica* branch at x running to the inside of the arme. cc, The common veine called *Mediana*. d, the partition of the *Median* veine about the wrist, but the d is set a little too low. e, s, The outward branch heereof going to the outside of the hand at y, from which yssueth a small branch vnto the inside of the hand at s. z, Another branch towards the middle and ring Fingers. g, The veine of the Thumbe which nourisheth the Hillocke or mountenet which ioyneth with the veine noted with s.

propagations: the most noble whereof is disseminated into the muscles which lye vpon the chest, and of these againe the largest called *Thoracica inferior*, [tab. 9. k.] the lower chest veine, runneth neare the ribs, and receiueth the rootes of those veines which issue out of the chest, and whereby (we said before) the distances betwixt the ribs were nourished: or to speake plainer, the mouth of the veine *Azygos* doth ioyne in three branches, sometimes in foure on each side with the mouth of the chest-veine. [tab. 8. xxx. with yyy.]

Hence any man may gather what veine is to be opened in a *Pleurisie*, that is to say, whether the veine on the side inflamed or on the contrary side.

It sendeth also a small branch vnto the muscles which extend or stretch the cubit, [tab.

Tab. 9 n] against which another veyne is disperfed from his oppofite into the Glandules. From the fame backefide another veine [*Tab. 9 O*] is fent to the fame mufcles, from which fome furdles are fprinkled into the fkinne of the Arme on the outfide. Vnder this a notable propagation [*Tab. 9 p*] runneth obliquely downeward vnder the bone of the Arme toward the outward protuberation together with the fourth nerue of the arme.

The diuifion
of the *Bafilica*.

Profundus.

His diuifion.

Subcutaneus.

His diuifion.

Afterward this *Bafilica* not farre from his egreffe out of the cauity of the Cheft, is diuided into two trunkes [*Tab. 9 fig. 1 q r*] and thofe almoft equall, one of them is called the Deep veyne, the other the *Cutany* or *Skinne* veyne. The Deepe veyne becaufe it lyeth or lurketh in the bottome is called *Profundus* [*q*] or the trunk which lyeth low. It is faftned to the Axillary Artery which runneth into the arme [*ta. 9 fig. 2 n*] and their diftributions are almoft alike. It is alfo accompanied with the fourth branch of the third nerue of the arme, and defendeth through the middeft thereof vnder the *Median* or common veine, and when it hath overcome the ioynt of the cubit; [*tab. 9 **] it is diuided into an vtter and an inner branch, which receding or departing a little one from another, and fprinkling furdles into the mufcles, do defcend together with tendons of the mufcles of the fingers vnder the tranfuerfe ligament, and are diftributed into the infide of the fingers. The vtter, which defcendeth along the *Radius* or wand lendeth 2. fmall branches to the thumbe and the fore-finger, and one to the middle finger. The inner, is tyed to the bone of the cubit and is deuided alfo into two; and from thefe one branch is afforded to the middle finger and 2. to the Ring and little fingers. The firft to the mufcles of the outfide of the hand, the 2 to thofe on the infide.

The other trunk of the *Bafilica* [*tab. 9 r*] is called *Subcutaneus* or the skin-veyne, becaufe runneth immediately vnder the fkin throughout the length of the arme on the infide, and in his paffage difperfeeth many branches; afterward a little about the inner protuberation of the arme where it is no leffe conspicuous before diffection then the *Cephalica* is about the cubit; it is diuided into a forebranch [*tab. 9 t*] and a hinder branch. [*tab. 9 a little about u*] The fore branch running obliquely through the middle of the bought of the cubit, maketh together with the inner branch of the *Cephalica* [*tab. 9 H*] vnder the bent, the Common veine. [*tab. 9 a*] Yet fometimes this branch which runneth vnto that common-veyne is farre larger or leffer then the branch of the *Cephalica*, fometimes alfo either of them are double. The pofterior branch of the *Skin-veyne* [*tab. 9 u*] is diuided into two neere the inner protuberation of the arme, [*vnder u*] and the vtter and greater of thefe [*xx*] defcendeth along the *vlna* or Ell vnto the wrefte, and fendeth a branch downeward [*xx*] neere the wrefte vnto the little finger, and againe meeteth and ioyneth [*l*] with another branch of the *Cephalica* [*i*] paffing that way, and this after the manner we haue before fpoken of vs diftributed into the out-fide of the hand. From this branch alfo a furdle is diffeminated vnto the fkin [*y*] and the back-parts. There are alfo other branches [*the lower z*] yffuing out of this propagation [*u*] diffeminated into the fkin of the infide, which branches are diuerfly mixed now vniting themfelves, againe departing one from another, affuming furdles from the propagation noted with [*x*] and communicating others vnto it.

Burften veines
in the armes.

An idle curio-
fity.

Finally, from that branch of the *Bafilica* [*tab. 9 t*] which maketh the *Mediana* or common veine, out of the lower and middle part thereof yffueth another notable veine [*at the upper z*] which defcendeth fometimes direftly fometimes with a crooked paffage vnto the wrefte, and is diuerfly vnited with other neighbour veines. Hence it is, faith *Vesalius*, (and the obferuation was worthy of the Authour) that fometimes the infide of the cubit is troubled with broken or boddene veines as the calfe of the Leg is. The furdles of that notable veine fometimes direftly or in a right line, fometimes overthwart, fometimes obliquely, fometimes againe vnited and fometimes diuided, doe grow vnto the fkin of the infide of the hand.

From thefe fo diuers coniunctions of veines, efpecially when the beginnings of the *Cephalica* and the *Bafilica* is one and the fame [*Table 9 m n out of I*] we may eafily gather how vnprofitable a thing it is to be fo fcrupulous and anxious in the choyce of veynes in one and the fame fide of the arme: wherefore when wee are refolved to open a veyne, and a veyne of the arme, as alfo on which fide it fhall be performed, it will be out of doubt the beft to ftrike that veyne which vpon the binding of the arme will bee moft turgid and full. For there are three places to let bloud in the arme, according to *Galen* in his Booke *de curati-one per fanguinis miffionem*, the interior, the exterior and the middle. Wherefore when we come to open a veyne we find all three places equall or two onely, or all vnequall, fometimes alfo one of them is hidden and fometimes two. The fection of the inner veyne hee efteemeth profitable for thofe that haue any affection in the lower parts of the necke. The

fection

section of the vter veine when the superior parts as the face and the head are diseased. The section of the middle veine communicateth with both, for it is compounded of veines issuing on both sides.

To conclude, there are found in the *Cephalica* and *Basilica* certaine values, but I containe my selfe, for because we shall meet with them also in the foot, I thinke it best to referre their description vnto the end of our discourse of the Veynes.

CHAP. X.

Of the veynes of the whole Foote in the large acception.

THE hollow veine in the lower Belly descending vnto the Holy-bone, when it cometh vnto the fourth racke-bone of the Loyues, where it lyeth vnder the great Artery [tab. 10 O] is diuided into two equall trunks: one of which goeth to the right legge, the other to the left, which trunks before they get out of the *Peritoneum* are called *Iliaci*, [tab. 10, betwixt O and G] and presently both the right and the left are subdivided into two branches, [tab. 101] an interior and an exterior, from which diuers propagations are dispersed, as we haue before touched in the eight Chapter of the third booke.

From thence it beginneth to be called *Cruralis* or the veine of the Leg, [table 10 g.] and after the externall braunch [p] hath attained with two boughes vnto the bone of the Leg, it passeth the share-bone [•] and sendeth a circle vnto the *Cup* of the Hippe to be diffused into the muscles of that place which compasse the inside of the Thigh, and so a branch of it runneth vnder the skinne of the Thigh on the same side. Presently after it is ioyned [x] with the internall *Crural* branch [char. 2] and so ceaseth. But because in that place toward the lower part of the Thigh, there is a cavity wherein the branch of the hollowed veine was to be diuided into many propagations, that those propagations might be more firmly secured, there are many Glandules disposed round about, which also are a defence to the Nerue and the Artery that descend that way with the Veine.

From the *Crural* branch [table 10 G] which is the trunk of all the rest of the Veines that run into the Leg, and issueth from the outward branch [table 10 C] of the trunk of the Hollow Veine, there issue on either side fixe branches.

Division of the crural veine into fixe branches.
1 *Saphena*.

The first is called *Saphena* or the branch of the Ankle [⊙] which is a notable and very long Veine. It runneth together with a Nerue fastned vnto it through the inside of the leg, betwixt the skin and the panicle vnto the knee and so on toward the inward ankle, and is diuersly diuided into the top of the foot toward the Toes, especially toward the great Toe where it is mingled with other Surcles sent from other Veines into that place.

From this branch commonly there are foure propagations sprinkled through the skinne. The first is double, one interior [^] which being yet in the groyne sendeth on either side branches to the inside of the Thigh, to the groyne it selfe, and to the rimme of the belly. The other exterior [z] and larger then the former, determining into surcles which are sent into the foreside and outside of the Thigh.

4 Propagations.

The second propagation at the middle of the legge [11] reacheth to the muscle of the *Tibia*.

The third is rowled orbicularly backward at the knee, and one part of it goeth to the skinne of the whirle-bone, [z] the other into the Hamme: and this branch is altogether wanting when the veine of the Hamme is a little larger then ordinary [Char. 6.] or if it be not wanting it is exceeding small and slender.

The fourth departeth with surcles forward and backward at the middest of the *Tibia*, [tab. 10. from 9 to 10] which circles doe diuersly vnite themselues with the veines that are next vnto them, and are againe parted asunder. Sometimes from the inner part of the *Tibia* vnder the foreside of the Ankle, it is reflected and runneth vnto the vpper side of the foot [v] and is distributed almost into all the Toes of the foote; but the surcles about the foote and at the Toes doe differ much. For in some bodies it is mixed with other branches, and runneth out vnto the little finger: sometimes it runneth towards the Thumbe and the forefinger; wherefore scarce any man hath the same distribution of the Veines

Table 10. Sheweth the distribution of the hollow veyne into both the feet.

TABVLA X.

1 *Muscula*, the vter and lesser branch hereof runneth vnto the 2 and 4 muscles of the leg. 2, the inner and greater branch of the *Muscula* distributed through the muscles of the thigh, especially the first and the third of the leg. 3, 4, 5, Two crurall branches 3, 4, meeting together; furcles passe at 5 backward to the skinne of the thigh, and descend through the middle of the Hamme. 6 *Poplitea*, the hamme-veyne, which veyne the Ancients did often open. 7 Small branches from the hamme-veyne which runne through the skinne of the Calf vnto the heele. 8 *Suralis* or the Calf-veyne. It is diuided at the lower side of the thigh into an exterior trunk, 9, and an interior, 14, 9, 10, The vter branch of the surall veyne at 9, distributing a small branch outward into the skinne of the knee. 11, the diuision of the externall surall branch vnder the knee into an inner branch 11 going betwixt the muscles of the foot. 12, 13, And an vter which runneth through the outside of the leg vnto the outward ankle and the vpper part of the foot in diuers furcles. 14, 15, 16, the inner surall branch 14 runneth through the backside of the leg, a branch of the same through the inside of the leg at 15, which descendeth to the heele and the great toe at 16. 17, 18, *Ischias maior* issuing from the inner branch of the small veyne at 14, and passing vnto the muscles of the Calf. From this a great branch 18 is distributed into the vpper side of the foot and the toes passing downward betwixt the muscles of the leg. 19, The remainder of the inner trunk, 14 which runneth behind the inner ankle, and is consumed into the toes. 20, The coniunction of the externall surall branch with the branches of the *Poplitea* or the hamme veyne.

Veynes in both his feet, the same number and the same magnitude.

This veyne Physicians vse to diuide in the diseases of the wombe, especially in the retenti-
on of the courses, about the ankle.

The second branch of the Crurall veyne is called *Ischias minor* [tab. 10. α] and is opposite
to the former, for as that is the inner branch of the Crurall trunk, so is this the exterior.

α , The diuision of the hollow veyne at the fourth
spondell of the loynes about the holy-bone into
two Iliacke trunks, which diuision is like the
greeke letter Δ .

β , *Muscula superior* disseminated through the mus-
cles of the loynes, of the *Abdomen* and the *Perito-
neum* or Rim of the belly.

γ , the byfurcation of the first Iliacke trunk into an
exterior branch at σ , and an interior at ρ .

τ , *Muscula media*, a propagation of the branch ρ in-
to the outward muscles of the thighs and the skin
of the Buttocks.

χ , the meeting of the branch ρ with the veyne of
the second branch.

ψ , the passage of the branch ρ through the hole of the
share-bone.

ϕ , the Crurall veyne which is the stocke of the veynes
that goe into the leg.

Γ , *Epigastica*, a propagation of the branch σ carried
vpward to the muscles of the *Abdomen*.

$\Delta\Delta$, *Pudenda*, A propagation of the branch σ , which
runneth ouerthwart to the Genitals.

Θ , the veyne of the Ankle called *Saphena*.

Λ , the interior branch of the *Saphena* going to the
inside of the thigh, to the groynes and the *Perito-
neum*.

Ξ , the vter and greater branch of the *Saphena*,
going into the fore-side and outside of the
thigh.

Π , the second branch of the *Saphena* to the first
muscle of the leg.

Σ , the third branch of the *Saphena* rowled orbicular-
ly to the backside of the knee.

Φ , the fourth branch of the *Saphena* which runneth
vnder the skinne through the inside of the leg, and
is distributed into diuers furcles. And this branch
may here be opened.

Ψ , this branch should haue gone downe as farre as
char. 7.

Ω , *Ischias minor*, A propagation of the exterior
branch σ vnto the muscles that sit vpon the
ioynt of the hippe and to the skinne of that
place.

It is but a short veyne and is disseminated outward and ouerthwart into the fore-skinne of the ioynt of the hip and to the muscles of that place.

Afterward the trunk it selfe passing from the groyne is drenched among the muscles which compasse the bone of the thighs and shooreth out of it selfe the third veyne.

The third veyne is called *Muscula*, [Table 10, char. 1] and is double, sometimes they are swere one another. The viter and lesser of these [char. 1] parteth with surcles to the second and fourth extending muscles of the *Tibia* and into the skin. The inner and the greater [char. 2,] which also lyeth deeper, is diuicuated or diuersified through all the muscles almost of the thigh, especially the fift and the third extender of the legge, and at length assumeth the end of that veyne [et] which runneth through the hole of the shate bone into the thigh, wherewith being increased (but lurking still betwixt the muscles) it descendeth vnto the knee. But the greatest veyne called *Cruralis* [G] in the middle of the thigh, is by degrees writen backward and offers small surcles to the membranes of the nerues that descend vnto the leg. Afterward it parteth with the fourth veyne.

The fourth veyne is called *Poplitea* or the Hamme-veine, which is made of two crural branches vnited. [char. 3, 4] From this in his originall, certaine surcles are sent backward and vpward into the skin of the thigh, [char. 5] afterward it falleth directly vnder the skin through the middest of the bent of the hamme [char. 6] as farre as to the heele. [char. 7, the lower] Sometimes it descendeth to the skin of the outward ankle, sometimes also of the inner, from which in his progresse he sprinkleth many small branches vnto the skin of the Calfe, some right, some oblique and some transuerse vnequally commixed and vnited together. Sometimes we meete with it simple and single, and sometimes this *hamme-veine* [char. 3] assumeth vnto it selfe a branch from the veyne which is sent to the fift muscle of the thigh, [char. 2] and being ioyned therewith it runneth out into the skin on the backside of the thigh, and sendeth some surcles vpward. And this is the veyne which the Ancients vsed to open vnder the knee. The fift veyne of the Crural branch is called *Suralis* or the Calfe-veine. The great veyne of the legge at the lower end of the thigh, after it hath sent small branches backward on either side, [at char. 8] into the originall of the three muscles which make the Calfe, it is in the hamme diuided into an exterior and an interior trunk. The exterior [character 9] after it hath distributed a branch [character 10] obliquely outward toward the connexion of the *Brace* with the *Leg-bone* into the skin on the fore-side of the knee, is presently vnder the knee diuided into two branches; an interior [character 11] which descendeth with the *Brace* among the muscles of the foote, and it endeth where their fleshy part determineth, for it attaineth not to the skin: and an exterior, [character 12, 13] which running along the outside of the legge to the outward ankle and the vpper part of the foot, attaineth to the skinne, but the skin on the outside onely.

It distributeth also (as did the *Poplitea*) [char. 7] diuers surcles, and mingling it selfe [char. 20] with the surcles of the *Poplitea*, especially in the top of the foote which they call the *Backe*, it maketh that knarle of veynes which is seene in the vpper part of the foote vnder the skinne.

The Interior [character 14] descending directly through the backside of the legge looseth a branch [character 15] from his inside, which passing along by the inside of the *Tibia*, is disseminated vnder the skin vnto the inside of the heele and the great toe [char. 16] and is vnited to the surcles that are there-about, and afterward againe diuided from them as we haue said before that other veines do.

And this surely is the reason why in this part so often there are *Varices*, that is, bursten or boddene veynes. But this vnion and diuision or distraction afterward of the veynes was necessary, least when the skinne is offended and some veyne cut ouerthwart, the skin that bordereth vpon it should be destituted of nourishment. Wherefore because in the legge in three or foure places the internall veynes are vnited with the cutany veynes or veyne of the skinne (especially in the foot) if you purpose to open one of them that lye next vnder the skinne there is no reason you should be very scrupulous in your choice, as if they were peculiar veynes deriued from diuers parts or bowels of the body, for they are all propagated from one and the same trunk.

The Interior trunk [char. 14] when it hath sent forth the fore-said branch, [char. 15] runneth deepe and produceth the sixt veyne.

The sixt and last veyne is called *Ischias maior*, [char. 17] the greatest part wherof descending through the Muscles of the Calfe casteth on each side small surcles, and when it attaineth

neth to the separation of the bone of the leg from the Brace-bone, it sheweth out a great propagation [ch. 18] from his forepart, which having perforated the membranous Ligament runneth among the Muscles which occupy the forepart of the *Tibia*, and in his descent affordeth furcles to the neighbour muscles; and when it is past vnder the transverse ligament is distributed in the vpper part of the foot, but so, as it is divided into his Musculous substance, and so giueth to each toe two small branches. And this veine in the Sciatica & other affections of the Hip is vsually opened about the outward ankle; and *Falopius* giueth vs his word, that it is of great auaille though he rely more vpon experience then vpon any great reason.

A note for the
Sciatica.

That which remaineth of the interior branch [chap. 14] runneth into the backside of the foresaid muscles and so attaineth to the sole of the foote, where it is consumed into many small branches which run by courses. Two of them creepe along the inside of each toe, sometimes the little toe hath five, the next to it two, the middle toe one.

And thus haue we brought to an end the History of the veines throughout the whole body. Now we should passe on vnto the Arteries, saying that we promised in the end of the last chapter to say somewhat of the values which are found in the veines, which promise I will now acquit my selfe of.

CHAP. XI.

Of the Values or Flood gates of the Veines.

Anicen.

Aquapendens.

Salomon Al-
bertus.

These Values *Anicen* the *Arabian* seemeth to haue made the first mention, calling them *Cels in the Veines*. *Hieronymus Fabricius ab Aquapendente* an excellent Anatomist of *Padua* in *Italy* made publike demonstration of them in the yeare of Grace 1574. and wrote a Treatise of them in the yeare 1603. *Salomon* also *Albertus* shewed them in the yeare 1579 and wrote of them in the yeare, 1584.

Table xi. Figure 1. sheweth the Arme bound ready for blood-letting.

Fig. 2 and 3, sheweth two Veines of the legs turned the inside outward.

TABVLA XI.

- A, A branch of the *Cephalica* Vein, making the *Median* veine.
- B, C. The *Basilica* B, and a branch of it making the *Median* at C.
- D. The *Median* Veine made of the branches of the *Cephalica* and *Basilica*.
- E. The *Median* Veine being carried through the middest of the *Cubit* diuided about the *Radius*.
- F. A deepe trunk of the *Basilica* or the trunk lying very low.
- G. The trunk of the *Basilica* lying vnder the skin.
- HHH. Values in the veines of the Arme.
- I, K. The first veine of the Leg.
- L, M. The second veine of the leg.
- NNN. The values filled with hum-bast.
- OOO. The values empty.

The Values are of the core of the making in them as so thin as where outside then Valves floodgates which they are seated in the arms-branches which a their nourishment. distributed to other along the large or gated obliquely b They reach fra but vp the ori veine, but are ra been no regurgita in the orifice of th too much backwa The Trunke Artery hath no way distributed as as also for the gen veines are all tog

The orifice of the zz.

The Values are found in the Veynes of the ioynts, and are nothing else but small portions of the coate of the veynes starting in their cavity, and intercepting the one halfe thereof, making in them as it were an angle or corner: wherefore the body of the Veyne is no where so thin as where these small membranes do depart from it. Some men had rather call them *Ostiole* then *Valuula*, which word we do not better know how to English then to call them *Floodgates* which stoppe and intercept the currentsof waters.

What a valve is.

They are seated in the veynes of the arme and the legges above and below after the Glandules of the arme-pits and the groine. Presently vnder the originals or out shootings of the branches which are disseminated from the sides of the veynes into the neightbout parts for their nourishment. And the reason why they were created was, that the blood which is to be distributed to other parts, might in that place make a stay and not be carried in a full streame along the large or direct Canale or pipe, and so the lesser branches, and those that are propagated obliquely be defrauded.

Their situation.

And use.

They reach from the sides of the veines vnto the middle of their capacity: neither do they shut vp the orifices of the branches where they take their beginning out of the hollow veine, but are rather disposed in the branches themselves, for otherwise there could haue been no regurgitation of humors which is very necessary as we are taught by revulsions. But in the orifice of the Iugular veine there are found two Values, least when the head is reclined too much backward the blood should violently rush into the braine.

Where they are found.

The Trunke of the Hollow-veyne in the lower and middle Region, as also that of the Artery hath no Values, that without any obstacle or opposition the blood might be every way distributed as well for the restauration of the substance that vanisheth or wasteth away, as also for the generation of spirits. In like manner an innumerable number of small external veynes are all together without them.

TABVLA. XII. sheweth the values almost in the middle of the arme at the originall of the Inner Iugular veine.

- a, The subclavian veine.
- bb, The orifice of the veine betwixt the inner Iugular and the Axillary veine.
- c, Two values at the originall of the internall Iugular. d, The internall Iugular opened.
- e, The diuision thereof neere the head.
- f, The Glandule vnder the eare.
- g g g g, five ribs cut off.
- h, Values at the Axillary veine. i, The axillary veine produced from the Subclavian.
- k, The diuision of the axillary veine into the

- Cephalica and the Basilica.
- n, the Cephalica called also *Humeralia*.
- m m, two values in the Cephalica five fingers almost asunder.
- u, the muscle of the arme called *Deltoid*.
- o o, the Basilica veine called also *Hepatica*.
- p q r s, Four values, the first is four fingers off the second, the second three from the third, the third two fingers off the fourth.
- t, two values ioyned together in the Basilica.
- u, the Arme-pit or the hole vnder the arme.
- G g g g 2

The

The number of these Values is vncertaine and the distances betweene them very vnequal, yet commonly they are double or two together, vnlesse it be a little about the Transuerse Ligaments which containe the Tendons of the hands, the feete, the fingers and the toes. Also when a large veyne beginneth to be contracted there most commonly they begin to be fewer till at length they vanish quite away. For where it is fit that more blood should be stopped and stopped longer, there are two Values; where lesse and for a shorter time there one will serue the turne, specially there is but one where a lesse vessell is obliquely produced out of a greater.

Their distance

In the Cephalica
In the Basilica

For the distance betweene them, although they runne throughout the length of the vessell, yet in some places there is two fingers, in some three, in some foure, in some five fingers distance between them. As for example, in the *Cephalica* vnder the Muscled called *Deltoideus*, there are two Values about five fingers distant one from another. In the *Basilica* as it runneth through the inside of the arme there are foure large Values. The first is foure fingers distant from the second, the second three from the third, the third two from the fourth, after which follow two small Values ioyned together.

In the Veines
of the foot.

So in the foote, (I meane the foote in the large acceptation) in the Hollow-veyne before it be subdivided in the groine there are two great Values set, afterwards when it is diuided into a greater and a lesser trunk, the greater in two places hath two Values foure fingers distant one from another. Thence downward at the Ham one, at the calfe two, then one, and finally two other. But in the lesser trunk there are more, for in the beginning of the byfurcation there are Values; within the distance of two fingers, two more:

TABVLA XIII. sheweth the
crurall veine and Artery, as also
all the lesser branches of the Cruall
veine opened.

a, b, c, d. The Cruall artery diuided
through the midst which hath no
values.

e, f, g. The cruall veine opened.

h, two values in the cruall veine.

i, the diuision of the cruall veine into a
deeper or greater branch and an ytter or
lesser.

k, the deeper or greater branch.

l, The exterior branch or the lesser which
maketh the *Saphena*.

m, m, Two values in two places distant
one from another about foure fingers.

n, n, n, Two values in three places, the first
the beginning of the bifurcation, the 2
at two fingers distance, the 3 at three.

o, one value foure fingers distant from the
two last.

p, 2 values at the Hamme branch.

q, two values vnder the Hamme at the
distance of foure fingers, where there
is no branch.

r, One value, three fingers distant from
the former.

s, One other value foure fingers distant
from that,

t, u. The veine *Saphena*.

x, A value five fingers distant from the
former.

y, two values at the wrist of the foot.

z, a value three fingers distant from the
former.

a, the last value of the *Saphena*, for that
which remaines hath no values at all.

and

and two others three fingers off; likewise in the same veine making the *Saphena* there is one Value; foure fingers off of that two, and vnder the hamme foure fingers off likewise two more; three fingers off there is one, and another foure fingers off it; five fingers off that another, two vnder the wrest of the Foot; three fingers off them one single one, and after the same distance appeareth the last; the remainder of the *Saphena* runs without Values vnto the top of the great Toe.

But because the stronger current and course of the blood might be better abated, these Values are not placed in a right line or alwayes on the same side, for then the whole streame of blood would haue flowed downe that side of the vessell that is free: Wherefore they vary their seat very artificially, as if in the vpper part of the Veine there be two Values, then after the distance which we said was betweene them, other two Values appeare in the lower part of the Veine, so that the hotnesse of the following membranes doe regard the middle and embowed part of those that went before and on the contrary, yet so that in the middest they do not touch one another, but leaue a tract or path whereby the blood may passe downward and fall as well into the lower Values as into these aboue. So then the lower Values stay that blood which escapeth from the vpper, and yet the course of the blood is not yet intercepted.

The figure of a Value sayeth *Aquapendens*, is like the nayle of a mans finger, or they be like a horned Moone, on their outside they represent the knots that are in the branches of Plants, for when a mans Arme is tyed to let him blood, there appeare within certaine distances as it were knots on the outside, and in clownish bodies, sayth *Bauhine*, they may be scene to swell in the outside of the Legs like a *Varix* or a veine. And truely a *Varix* is nothing else but a Veine and his Value dilated by thicke blood which is detained in the Value, for without these the veines would be dilated and swell equally in euery place.

Vpward toward the roots of the Veines these Values are open, but below and at the sides they grow to the Veines, for they are portions of their coate. And if you put a quill

Table 14. sheweth the Values of the Crurall veine and his deepe branch which walketh along with the Arterie, and these values may here be scene as farre as the byfurcation.

TABVLA XIII.

- 1, The deeper branch of the Crurall veine which must be tyed with the branch marked with R in the former Table about d, which noteth the Arterie.
- 2, The Crurall Arterie which must be ioyned with d of the former Table.
- 3, Two Values with a propagation out of the Veine.
- 3 The hamme.
- 4, One great Value with a propagation.
- 4, The Calse.
- 5, Two Values without any branch.
- 5, One Value with one propagation on either side.
- 6, Two Values without propagations.
- 7, The Crurall Veines, and the subdivision of his deeper branch into 2, which also haue their Values though they cannot now follow them.

Gggg 3

into

into a veine, and lightly blow, then will the veine swell our like a little bladder, or rather it we may compare little things with great, like the sayle of a shippe when it runneth freshly before the winde.

Their substance.

Their substance is exceeding thinne that they might take vp the lesse roome, yet very thight and fast for more strength that they might not be broken by the violent incurfion of the blood.

Their vse.

Their vse is to stay the blood from falling too hastily into the lower parts, otherwise because the ioynts doe hang downward the blood would haue falne into them like a streame, and so the lower parts should haue bene oppressed by too great an affluence of Aliment, and burdened with a weight of humour, but the vpper parts should haue bene defrauded. Now by reason of these valves the Aliment doth subfist or make stay in the greater vesselles as it were in a founraine, that the smaller veynes might alwayes haue nourishment at hand to conuay vnto their particular parts.

Againe, because the veynes were created not onely to deriue or transport the blood into the parts, but also to adde something vnto the perfection of his concoction, there is no doubt but these values were ordained to stay the course and violence of the blood that the veines might haue time to bestow their trauell vpon it.

Thirdly they adde strength vnto the veines, for were it not for these, it is likely that where a *varix* hapneth, there either the veine would breake, or at least the dilatation be much more offensive. For because the veine is of a membranous, simple and thinne substance, it may easily be stretched or broken.

Fourthly, when we exercise our ioynts vehemently and often, the heat of the parts is stirred vp and the blood partly disturbed partly called into the ioynts, where the values do breake the force of it and so keepe it from mischief.

Finally, if it were not for them in those violent motions of the ioynts, the whole masse almost of blood would be called into the armes and the Legs, and so the principall parts or bowells of the body be defrauded of their allowance, and thus much of the Values. Onely, because, they are not so well known nor so ordinarily demonstrated as the other particles of the body, we haue exhibited in this Chapter 4 tables. Two of the Hand and 2. of the Foote, wherein the values of the veines are very liuely described; and so we proceed vnto the second part of this Booke which is concerning the Arteries.

The second part of the Eleauenth Booke

concerning Arteries.

CHAP. IX.

Of the Arteries in generall.

The names of an Artery.

As the Liuer is the beginning of *Radicacion* and *Dispensation* to the Veines, so is the Heart to the Arteries. This Artery the Grecians call *αορτη*, because it is as an Arke or Conceptacle of arteriall blond. *Aristotle* in his third Booke *de historia animalium* thinketh it was called *aorta*, because his neruous part may be perceiued euen in a dead body; others thinke it was called an Artery, *πρὸς τὸ τὸν ἀέρα τερεῖν*, that is, to draw ayre. Others *πρὸς τὸ ἀρθεῖν*, which signifieth to lift vp, for in their dilatation they do lift vp themselves: *Hippocrates* calls Arteries *αἰμαίνες*, but *micantes*, that is, bearing veynes. In like manner did the Arabians

stile them, and *Auicenna* calleth them *venas audaces*, bold veines. *Pliny* calles them *spiritus semita*, the path or walke of the spirites. Wherefore if in any of the Ancients which wrote before *Galen* you meet with the word Artery simply, then must you vnderstand it of the Rough Artery: for so *Hippocrates*, *Plato* and *Aristotle* did call that pipe which descendeth out of the mouth into the Longues, and leadeth inspirated ayre into them and by which we returne our breath out. But *Galen* & those after him called it *aspera arteria*, and if they speake of an Artery simply, we must vnderstand it of the smooth Arteries.

Three sorts of Arteries.

There are three sorts of Arteries: the first is called the *Rough Artery*, of which wee spake in the sixt Booke. The other is called the *Venall Artery*, of which also wee spake in the

the history of the heart. The third is called the great artery which is the subject of our discourse at this time.

We consider it therefore as it is a Similar and as it is an Organical part. As it is similar it may be defined *A Colde and dry part engendred of the slimy part of the Seede.* Colde it is of his owne nature, but by euent it is most hot in respect of the blood and spirits therein contained. It is dry also: lesse dry then a Tendon, and more dry then a Nerue.

An Arterie as it is similar.

But against this it may be Obiectioned, that *Galen* in his second Booke *ad Glauconem* saith, That *Nervous parts require more drying then Arteriall, and therefore are dryer then they.*

Obiection.

I answer, that by nervous parts in that place he doth not vnderstand nerues properlie so called, but nervous bodies as Ligaments and Tendons.

Solution.

If we consider an Artery as it is an organical part, it may be said to be a common instrument of the body, long, rounde and fistulated, compounded of two peculiar Coates, intertexted or woven with Fibres, receiuing and containing Bloode and Vitall Spirits laboured of a permixtion of Blood and Aire in the left ventricle of the heart, which also conueyeth vnto all the parts of the body, together with heat to sustaine their life.

Defined as Organically.

The substance thereof is membranous or nervous that it might better be distended or compressed, which conformation was more necessary for Arteries then for veins because of their motion.

The substance.

The coats are one outward which is thin rare and soft like the coate of a veine, woven with many right fibres and some oblique, but none transuerse. Another inward finefolded thicker then the former, fast and hard, partly that the arteriall and spirituuous blood (which is thin, pure and vaporuous) and the vitall spirit might not exhale or vanish away, partly that by reason of his continuall *Diastole* and *Systole* which it receiue from the Heart as from a beginning of dispensation it might not be broken. It is also full of transuerse fibres the better to distribute the blood and vitall spirit to the whole body in his action and motion, for the inner coate onely of the arteries hath these transuerse fibres. To these two coats *Galen* addeth a third in the fifth chapter of his seventh Booke, *De administrationibus Anatom.* which some say is produced from the coate of the heart. It is in the inner surface of the vessell much like a Cobweb and most conspicuous about the productions of the greatest arteries.

Coats.

Moreover, they receiue a common and fine membrane in the lower belly from the Rim, in the Chest from the *Pleura* which couereth them, firmeth them, or tyeth them to the neighbour-parts, yet those arteries which run through the bowels haue not this coat.

The great artery is sometime called simply *great*, sometime the *greatest*, sometimes the *thickest* artery, sometime *Aorta*, and is indeed the mother of all the rest of the Arteries, (except the Rough artery and the venall and vmbilical arteries) being like a trunk or body of a tree, out of which all the branches do yssue. It was engendred, saith *Bauhine* out of *Galen de formatione fœtus*, before the Heart was formed and hath one principle of Originall; that is, the seede out of which it is immediately made as being engendred at the same time with other spermatikall parts; Another of Dispensation and Radication which is the heart or the left ventricle thereof, out of which it yssueth with a patent or open Orifice, whereby it receiue from the heart in his contraction Blood and vital spirits together with heate to be transported to the body. But because in the dilatation of the hart this blood and these spirits should not returne againe into the ventricle, there are placed in his orifice three values issuing from within outwarde, as also there are in the arteriall veine. But these of the artery are stronger and greater, because the body of the artery is harder then that of the arteriall veine.

The great Artery.

His originall.

Values.

These values also do hinder the aliment which is drawne by the Meseraicke arteries from the guts, that is the Chylus, which *Hippocrates* in his Booke *De Corde* calls *Alimentum non principale*, as if he should say an aliment at the second hand, lest I say, this Chylus should get into the heart. The Orifice also of this artery is established with a hard substance which is sometimes gristly, in some greater creatures a bony gristle, for it is very rare if it be found a true bone, notwithstanding that *Galen* saith it is a bone in an Elephant, but in man there is no such thing found.

Hippocrates.

The branches of this great Artery are distributed into the whole body, as may appeare by this Table which we haue heereto annexed.

In this distribution of the branches of the great Artery they accompany the branches of the Gate and the Hollow-veynes, yet are their propagations not so frequent, because the Artery doth not alwayes accompany the veine, for those veynes that goe vnto the skinne haue no arteries with them, at least that are conspicuous. Again they are very rarely dif-

feminated

Table 15. sheweth the great Artery whole, and separated from all the parts of the body, together with his diuisions and subdiuisions.

TABVLA XV.

the little finger, the ring finger, and the middle finger. * A little branch vnto the muscles about the little finger. T. the distribution of the vpper and lower branches into the hand and the fingers. V. the trunk of the great artery ascending to the *Inguinum*, and the diuision thereof in that place into X, Y, Z. X. the left *Carotis* or sleepey artery. Y. *Subclavian dextra* is diuided into branches, as the right is diuided. Z. *Carotis dextra* called also *Apoplectica* and *Lebargica*. a, The diuision of the left *Carotis* in the Chops. b, the exterior branch of that diuision going into the face, the temples, and behinde the ears. c, the inner branch going to the throtle, the choppes and the tongue. d, the diuision hereof at the basis of the skull, into two branches which enter the *sinus* of the *Dura mater*. e, A propagation of the branch b, vnto the muscles of the face. f, the distribution of the branch b, vnder the roote of the ears. g, the fore-branch hereof creeping vp the Temples. h, the backe branch running on the backside of the eare vnder the skinne. i, the trunk of the great artery, descending vnto the spondels of the backe. k k k, The lower *Intercostall* arteries which goe vnto the distances of the eight lower ribbes, from which are offered surcles to the marrow, and to the muscles that grow to the backe and to the Chest. l, the artery of the midriffe called *Phrenica* or *Diaphragmatica*. m, *Mesenterica Superior*, but you must note that about m, the trunk of the *Celiacal* artery is taken away, lest the multitude of Letters in so small a table should breed obscurity. n, b, The right and left emulgents running from the *Aorta* or great artery vnto the Kidneys. n, n, The spermaticall arteries on either side going to the testicles. a, the lower *Mesentericall* artery on the left below m, running especially into the Collicke gut on that side. μ μ, The arteries called *Lumbares* which runne ouerthwart and like knees affording surcles to the muscles that grow to the Loynes, and to the *Peritoneum*. μ, the lower; *Muscula superior* running into the sides of the *Abdomen* and the muscles. ν, The byfurcation of the great artery into two *Iliacke* trunks, and at the sides but somewhat inward are branches which make those that are called *Sacra*. T, the diuision of the left *Iliacke* trunk into an inner branch at ξ and an ytter at φ. ξ, The inner *Iliacke* branch. o, *Muscula inferior*, the ytter propagation of the inner

- A, The orifice of the great Artery, or the beginning thereof, where it issueth out of the heart.
 B, *Coronaria*, so called, because like a crowne it compasseth the basis of the heart.
 C, The diuision of the great artery into 2 trunks V i.
 D, The left subclavian climbing obliquely vpperward vnto the ribs.
 E, the vpper intercostall artery, or a branch which bestoweth foure propagations vnto the distances of the lower ribs.
 F, the necke artery which through the transuerse processes of the rackbones of the necke, attaineth to the skull, bestowing circles vnto the marrow and his neighbour muscles.
 G, the left Mammery artery running vnder the brest-bone, and to the nauell. It distribureth surcles to the *Mediastinum*, the muscles of the brest, and of the *Abdomen*.
 H, *Muscula*, or a branch attaining to the backward muscles of the necke.
 I, The *Scapular* arteries which goe vnto the hollownesse of the blade, and of the muscles that lye thereon.
 K, *Humeralia* which climbeth ouer the top of the shoulder.
 L, *Thoracica superior* sprinkled vnto the forward muscles of the Chest.
 M, *Thoracica inferior*, which passing along the sides of the Chest, attaineth to the broad muscle of the arme.
 N, the axillary artery running out into the arme and affording branches vnto the muscles thereof.
 O, A branch reaching to the outside of the cubit lying deepe.
 PP, Branches to the ioynt of the cubit with the arme.
 Q, the vpper branch of the artery running along the *Radius* and offering surcles to the thumbe, the fore-finger and the middle finger.
 k, A surcle creeping vnto the outside of the hand and led betwixt the first bone of the thumbe and that of the After-wrist supporteth the fore-finger where we vse to feele the pulse.
 S, The lower branch of the artery running along the *Vlna* and communicating surcles to

inner branch going vnto the muscles which couer the branch bone and the *Coxendix*. *π*, *Hipogastrica*, the inner propagation of the inner branch going to the bladder, the yard and the necke of the wombe. *ρ*, The vmbilicall artery. *ς*, The remainder of the branch & assuming an addition from the vtter branch neare *ο*, and so falling through the hole of the share bone into the leg. *τ*, *Epigastrica*, it ascendeth v pward vnto the right muscle of the *Abdomen*, and about the nauell is ioyned with the mammary artery. *υ*, *Pudenda*, it creepeth ouerthwart the share bone. *φ*, The *Crural* trunk without the *Petitonium*. *χ*, *Muscula cruralis exterior*, going into the fore muscles of the thigh. *ψ*, *Muscula cruralis interior*, going vnto the muscles of the inside of the Thigh. *ω*, The coniunction of this artery with the branches. *Γ*, *Poplitea*, going to the muscles on the backside of the thigh. *ΔΔ*, which communicateth small branches to the ioynt of the knee, and the muscles that make the Calf of the Leg. *Θ*, the diuision of the *Crural* artery vnder the hamme into three branches. *Α*, *Tibia exterior*, it accompanieth the *Brace* bone, and is consumed into the muscles. *Β*, the chiefe part of the *crural* artery. *Ξ*, the vpper and backer *Tibia*. *Π*, the lower and backer *Tibia* running vnto the vpper side of the foot at *Φ*. *Ψ*, A propagation of the *crural* artery going to the inner and vppet side of the foote and sprinkling a branch vnto the ankle. *Ω*, A propagation vnto the lower part of the foot which affordeth surcles to each Toe.

diffeminated into the muscles, but creepe onely on their outides, because the thinne blood of the arteries, and their subtile spirits when they issue from them, are able to insinuate themselves farre into the substance of the part without the helpe of a vessell.

The arteries why fewer then the veins.

CHAP. XIII.

Of the use of Arteries.

THe use of the great Artery and of his branches may be considered two wayes; either as they are Canales or Pipes, or as they moue and beat perpetually. As they are Canales or Pipes, they haue three vses or ends. First to containe spirittuous and vitall blood, and to distribute it vnto the whole body, partly for the perfect nourishment of the particular parts, for the parts (saith *Galen* in the tenth Chapter of his sixt Booke, *De usu partium*) which are neare vnto the Arteries doe draw out of them vaporous blood though it be but little, partly for the nourishment and generation of the animall spirits.

A double consideration of their vse.

3. vses as Canales

The second vse is to leade vnto the parts vitall spirits, to cherish and sustaine those vitall spirits which are seated in the parts. Thirdly, with the same spirit to transmit heate and the vitall faculty perpetually into the whole body, to cherish the in-bred heate of the particular parts, to moderate and gouerne their vitall functions and to defend their life.

As the Arteries doe beate, so haue they also a treble vse. The first is to preferue the in-bred heate of all the members which they doe by ventilation or wafting aire vnto them. For if it were not breathed, it would by degrees languish and be extinguished. Their second vse is by their motion to make a kind of commotion in the blood (for the arteries accompany the veins) which if it were at rest would putrifie like standing waters, for blood, saith *Hippocrates*, is water. The third is to sollicite and to constrain the blood to fall out of the Veines into the substance of the parts for more speedy nourishment.

3. vses in respect of their motion.

This motion of the Arteries is called *pulsus* or pulsation (of the word *Hippocrates*, as *Galen* witnesseth, was the first Author) which is absolutely absolued by dilatation and contraction: qualities not bred with the artery or seated in their substance, but flowing into them from the heart, which may be demonstrated if you intercept a part of an artery with a tye, for the part that is vnder the tye will haue no motion, but as soone as the tye is taken away, the motion will returne.

Pulsation

Erasistratus conceiued that the Arteries moued quite contrary vnto the motion of the heart: but we agree rather with *Herophilus*, *Aristotle*, and *Galen*, who thinke they are dilated and constringed in the *Diastole* and *Systole* of the heart: onely wee must remember, that the motion of the heart is swifter and more vehement then that of the Arteries, which you may thus make experience of. Lay your right hand vpon your heart, and with your left hand touch the wrest of your right hand, and then you shall perceiue whether the motion of both be the same or contrary, but the more certaine knowledge of this point is taken from the dissection of liuing creatures.

In the contraction of the Arteries they strongly drive vitall spirits into the whole body

dy

dy and expell by expreffion foety and smokie excrements arifing from the humours which otherwise would fuffocate the heate. When they are dilated they snatch from the heart fpirits as a new matter which in their contraction they communicate to the particular parts to be a vehicle of the heat, and do affume out of the neighbour veynes naturall blood for their proper nourifhment by the inoculations which are betwixt them and the veynes, and that is the reason efpecially why the veines & the arteries do walke together throughout the whole body vnleffe fome great obftacle be in the way. But the arteries lye vnder the veynes vnleffe it be at the holy-bone, not fo much for defence as becaufe by their motion they might conftaine the veynes to powre out their blood, as alfo to make a confpiration or confent betwixt the veffels, and a communion of their matters that the arteries might afford vnto the veynes fpirit and life, and the veynes vnto the Arteries naturall blood.

Why they lye
vnder the
veynes.

Againe, by this vicinity of the veffels the membranes which couer the veines and tie them vnto the parts by which they paffe, are alfo of great vfe vnto the Arteries.

It is alfo thought that thefe Arteries by the pores of the skin do draw Aire whereby the heate which is within is breathed, which breathing is called Transpiration. But concerning the motions of the Arteries and by what faculty they are moued, whether they moue as the heart moueth, or contrary vnto it, we haue intreated in the fecond, third, fourth, and fifth Questions of the Controuerfies of the fift booke, to which places we referre the Reader.

CHAP. XIII.

Of the ascending Trunke of the great Artery.

The great
Artery.

THE great artery at the left ventricle of the heart from whence it arifeth, is exceeding large, whence Hippocrates, Plato, Aristotle, and Galen haue all agreed that the heart is the fountaine and originall of Arteries [Table 16 fig. 1 A] and before it fall out of the Pericardium or purfe of the heart about the valves, [Table 16 fig. 3 char.

The coronary
Arteries.

1, 2, 3] it affordeth fometimes one fometimes two coronary arteries, [Table 16 fig. 1 BB] which like a Crowne do compaffe the Basis of the heart, and through the length thereof together with the veyne difmiffeth branches which are more and larger in the left fide, and thofe make the fubftance of the heart viuide or liuely. Prefently after, a little vnder the trunk of the Arteriall veyne, it arifeth vpward and pierceth through the Pericardium, and is diuided into two vnequall parts, one of which ascendeth vpward [Table 16 fig. 1 E] vnto the head which is the leffer, the other and the greater by much runneth downward [Table 16 fig. 1 D] becaufe the parts of the creature which are vnder the heart are more a great many and greater then thofe that are aboue it. This trunk is proportionably answerable to the flock or body of a tree, and inclineth vnto the fift rackbone of the cheft, & declining a little to the left hand to giue a way vnto the hollow veyne, it descendeth vpon the rack-bones vndiuided, which part Aristotle properly called *Aorta*, becaufe euen in dead bodies the neruous part thereof was confpicuous, haply becaufe it is like to a Macedonian fheath which is called *κορτη*. *Praxagoras* vfed to call it *Craffa* or the thicke Artery. From this trunk, branches are difperfed which accompany the branches of the gate and hollow veynes into the whole body.

The greater
Trunke.

From the greater trunk therefore [Table 16 fig. 1, D] which in the cheft is largeft and thickeft, do iffue thefe branches following.

Intercostales
inferiores.

The lower intercoftall Arteries [Table 16 fig. 1, HHH] which proceeding in order from his hinder fide, are fent on either hand to the diftances of the eight lower ribs, as far as to their griftles: and thefe againe do diftribute furdles to the mufcles which grow vnto the back and cheft, and to the fpinall marrow through the holes which are made in the rack-bones for the out-lets of the nerues, after the fame manner that the veyne *Azygos* diftributeth his branches: for it is very rare to find the veyne *Azygos* accompanied with an artery iffuing from the *Aorta*, and then it may well be called *Intercostalis maior*, or the great intercoftall artery.

Phrenica.

Secondly iffue the artery called *Phrenica* on either fide one, [Table 16 fig. 1, KK] which is diffeminated through the midriff, and from thefe are fmall branches fprinkled alfo to the Pericardium where it groweth to the midriff. Sometime this *Phrenica* arifeth from the trunk vnder the midriff. The reft of the trunk that remaineth paffeth through the fiffure of the midriff [Table 15 fig. 1, *] cleauing to the bodies of the rack-bones, & from it are many propagations diftributed throughout the lower belly, of which we fhall fpeake in the next chap. and in the 16.

From

From the lesser and ascending trunk [table 16 fig. 1 E] which amongst the separating membranes lieth vnder the hollow veine and resteth vpon the rough artery, are branches communicated to all the parts about the heart.

First of all it sendeth on either side a notable branch which vnder the collar bone attaineth vnto the first rib of his owne side, and therefore it is called the *Subclavian* artery. Afterward the whole trunk departeth into the two sleepey arteries.

The right *Subclavian* artery [table 16 fig. 1 F, whose originall is at a] issueth out of the *Aorta* where it is diuided into the sleepey arteries: and this is the higher and larger branch, and runneth more ouerthwart then the left which ariseth much lower where the *Aorta* is retorted downward and attaineth more obliquely vnto the arme.

The right
subclavian
artery.

From either *Subclavian* before it fall out of the cavity of the Chest (for when it is out of the Chest it is no more called *Subclavian* but *Axillaris*) [table 16 fig. 1 PP] as soone as it toucheth the first rib and not before, are propagations deriued from the lower part; first.

Table 16, is the same with Table 13.

The vpper intercostall [table 16 fig. 1 II] which being fastned to the roots of the ribs communicateth particular branches to three or foure distances of the vpper ribs on his owne side; (but not alwaies after the same manner) from which surcles are distributed to the marrow of the backe and to the Neighbour-muscles. From the vpper part doe issue.

Intercostalis
superior.

First the *Mammaria* or the Artery of the paps [table 16 fig. 1 LL] which being reflected vnder the brest-bone descendeth accompanied with a Veine vnto the papes and the muscles [table 16 fig. 1 CCC] which occupy the distances of the gristles of the true ribs. It sprinkleth also surcles into the Glandules and the parting or diuiding membranes vnto which it adhereth, and at the side of the gristle called the brest-blade issueth out of the Chest and runneth vnder the right muscles of the *Abdomen* dispersing his fauors into the sides. At the Nauell it is diuided into many surcles, [table 16 fig. 1 dd] and is ioyned with the Epigastricke Artery which plyeth vpward. [table 16 fig. 1 ee.]

Mammaria.

The next artery which ariseth from the vpper part of the *Subclavian* trunk is called *Cervicalis* or the artery of the necke. [table 16 fig. 1 MM] It issueth more backward toward the bodies of the racke bones, sometimes from the sleepey artery, and ascending vpward when it hath attained vnto the seuenth rack-bone of the necke, it passeth through the holes in the transuerse processe of the said rack-bones, for which cause also Nature made them perforated; and distributeth his surcles to the muscles, the marrow of the necke, & to the Rack-bones. These surcles go in where the nerues get out. There is also an artery which perforating the membrane of the marrow betwixt the first racke and the Nowle-bone [table 16 f. 1 NN] entereth on both sides into the scull, ioyneth with his opposite and runneth along the basis of the Braine.

Cervicalis.

The third is called *Muscula* [table 16 fig. 1 OO] It sendeth branches vnto the Muscles which lye vpon the necke as farre as the nowle: sometimes also to the Muscles of the Arme.

Muscula.

After this trunk hath gotten out of the cavity of the Chest, we said before that it getteth a new name and is called *Axillaris*. From the axillary Artery therefore [table 16 fig. 1 PP] before it attaine vnto the arme there issue three Arteries.

Axillaris arteria.

The first is called *Thoracica superior* [table 16 fig. 1 QQ] which runneth on either side with abundant surcles vnto the Muscles which lye vpon the brest, and next vnto these are those small shootes which are allowed to the little glandules vnder the Arme-pits.

Thoracica
superior.

The second is called *Thoracica inferior* [table 16 f. 1 RR] which runneth downward all along the side of the chest, especially into that muscle which is called *Latissimus* or the Broad muscle.

Thoracica
inferior.

The third is called *Scapularis* [Tab. 16 fig. 1 S] which is disseminated into the Muscles reposed in the hollow side of the shoulder-blade. From the vpper part of the Axillary branch ariseth an artery called *Humeraria* [tab. 16 fig. 1 TT] which climbeth to the top of the shoulder, and is distributed to the Muscles which occupy the arme and the gibbous side of the blade. That which remaineth of the axillary artery [tab. 16. fig. 1 VV] runneth away vnto the arme being accompanied with the axillary veine whose diuisions we shall finde in the 19 chapter.

Scapularis.

Humeraria.

The remainder of the ascending trunk [tab. 16 fig. 1 E] resting it selfe vpon the rough artery toward the vpper part of the brest-bone being yet in the cavity of the chest is supported with the *Thymus*, and diuided into two vnequall branches which they call *Carotides*

[ta. 16.

[table 16 fig. 1 X T] or *Soporaes* the sleepey Arteries. These tend directly vpward, so that the right as also the left run through the sides of the necke vnto the basis of the scull being tied to the rough Artery and the internall Iugular veynes with a membrane, (for the Externall Iugulars are without arteries) and so reach vnto the head where we shall finde them in the 17 chapter.

CHAP. XV.

Of the descending trunk of the great Artery accompanying the Hollow Veine.

7 branches before the diuision.

THE Trunke of the great Artery [Table 17 L] at the eleuenth racke-bone of the Chest passing through the Midriffe [Table 17 char. 4.] runneth through the lower belly leaning vpon the left side of the bodies of the racks, and lying vnder the left side [table 17 L] of the hollow veyne [Table 17 K] declining somewhat to giue roome thereunto, and before it come to the last Racke saue one of the Loines, in some bodies at the Holy-bone [table 17 char. 14] where it is diuided into two trunks, it affoordeth seuen branches, whereof some do accompany the branches of the Gate-veine, as that called *Celiaca* and the double Mesentericall branch which depart vnto the Stomacke, the Mesentery and the Guts, of which we shall speake particularly in the next chapter.

Others accompany the branches of the Hollow-veyne couered with the *Peritoneum* or Rim of the belly, of which we shall intreat in this chapter. For Nature almost alwayes diuideth the Arteries where she diuideth the Veines, partly that the membranes wherewith she couereth the Veines and fastneth them to the neighbour parts might be of vse likewise vnto the Arteries, partly also that there might be a conspiracy between the vessels and a communion of matters, for there are few Veines without arteries ioyned vnto them vnlesse it be those that run immediately vnder the skin. Now the order of the branches as they arise out of the trunk is on this manner.

The first is called *Celiaca* [table 17 char. 6.]

Celiaca.
Mesenterica
superior.
Emulgens.

The second *Mesenterica superior*. [Table 17 char. 10]

The third *Emulgens* or *Renalis*, the artery of the Kidneyes [Table 17 d e] one left and another Right, sometimes but rarely we finde three or foure or more. This is a notable branch and well nie the greatest of all that arise from out of the great artery. It issueth out of either side of the trunk where the first and second rack-bone of the Loins are coupled with a Ligament, and pacing obliquely at the cavity of the Kidneyes it is diuided as the Veines are, and so implanted therein and therein consumed, imitating for the most part the distribution of the Veines.

Their vse.

Their vse is not so much to leade vitall blood as to purge away the whey from the vitall blood of which there is abundance in the great artery. Notwithstanding the fat membranes of the Kidneyes though they be neere at hand, doe not scarse at all partake of these arteries.

Spermatica.

The fourth is called *Spermatica*, the seede artery. [Table 17 char. 11] Both of them issue together (for their originals do touch) out of the forepart of the trunk, and descending the right rideth over the trunk of the hollow veine, and is fastned vnto the spermatieall veyne of his owne side (as the left is to the left) by the mediation of the *Peritoneum*. Afterward in men they passe the productions of the same *Peritoneum* and are applyed with a winding passage to the Testicles, whereto as also to their coats they affoord furcles. The vse of which application is to leade vnto them venall and arteriall bloode and vitall spirits. But in women the one halfe goeth to the Testicles, the other vnto the body of the wombe. And from these *Columbus* thought the vmbilicall arteries had their originall, but what reason he had for his conceite there I leaue him.

The fift is called *Mesenterica inferior*. [Table 17 char. 12]

Mesenterica
inferior.
Lumbaris.

Table xvij. is the same with the eight of the third Booke.

The sixt is called *Lumbaris*. [Table 17 the upper mmm] These are two arising out of the backside of the Trunke where it ioyneth to the rackbones & run crookedly through the holes of the racks of the Loynes and are distributed vnto the spinall marrow, as also to the Neighbour-muscles and to the *Peritoneum*. These also at the sides of the marrow together with the veines run vpward to the braine. *Columbus* maketh mention of no more branches before the diuision of the great artery, but *Laurentius* whom *Baubine* also followeth addeth a seuenth.

The

CHAP. 15. The descending trunk accompanying the hollow Veine.

The seventh therefore is called *Muscula superior* [tab. 27 the lower mm] which also is referred to the *Lumbares*, but larger then the rest and runneth out vnto the sides of the *Abdomen*, and blesteth his muscles with abundant furcles,

After these branches are distributed, the greater artery at the beginning of the Holy-bone [tab. 17, char. 14] climeth ouer the hollow veine, not as challenging the superiority, but because being perpetually moued it might haue beene offended if it had beaten against the bare bone.

At this place by reason of the parts through which it passeth it is called *Iliaca*, [tab. 17, r] and as the hollow veine so is it deuided aboue the body of the fourth Racke of the Loynes into two trunks after the manner of λ inuerted or turned vpside downe. Vnder this bifurcation yssueth the artery called *Sacra* [tab. 17, 00] whose furcles runne through the holes of the holy bone vnto his marrow. Not far from the deuision each trunk [tab. 17, p] is deuided into an interior or slender branch [tab. 17, s] and an exterior or greater [tab. 17, 5] which falleth vnto the Leg. From the interior branch yssue two propagations, one vter the other inner.

The vter is called *Muscula inferior* [tab. 17, ss] and runneth transuersly [table 17, f] outward betwixt the holy-bone and the bone of the hip, and is distributed with many furcles into the muscles which couer the haunch-bones and the hippe-oynt. In like manner at the groyne from one of the trunks ariseth a notable branch which runneth vnto the skin and cheriseth the *Cutany* parts which appertaine vnto the share, to the hanches and to the *abdomen*.

The inner is called *Hypogastrica* [table 17, u] which is the largest of all the rest, and runneth directly downward to the lower part of the *Os sacrum*, to the bladder and his necke, (some say also to the fundament, and may there be called the *Hemeroidall* arteries) and finally to the muscles which couer the share-bone, into all which parts his furcles are distributed.

In women this *Hypogastrica* is yet larger, and is distributed abundantly into the bottome of the womb. It sprinkleth also the neck thereof and the bladder with smal furcles. It sendeth forth also a branch which vnder the bifurcated originall of the yard runneth strangely intangled to his two hollow bodies, so making a kinde of web or complication and passeth vnto the nut. The remainder of the interior branch [table 17, p] creepeth downward, and admitteth vnto it the vmbilicall artery [table 17, at x] which passeth throughout the length of the great artery, and at the sides of the bladder for more strength is tyed with strong membranes, by which vmbilicall artery the Infant in the wombe liueth and enioyeth Transpiration, but after the Infant is born it turneth into a rye or ligament of which we haue spoken sufficiently before.

Presently after when it hath assumed a propagation which is sent obliquely downward from the external branch [ta. 17, s] where it is about to fall into the Legs [ta. 17, y] it passeth through the hole of the share-bone, and is dispersed into the muscles which occupy that hole, and into those that neighbour about it.

The Exterior branch of the byfurcation sendeth out two branches, one before it hath passed the *Peritoneum*, another after.

The first is called *Epigastrica*, [T. 17 char. 22] and reflected vpward, climeth ouer the right muscle, and his especiall branches about the Region of the Nauell are ioyned with the mammary; the rest of his furcles he disperfeth transuersly into the lower side of the *abdomen*.

The second is called *Pudenda* [Ta. 17 char. 15] a little branch not deuided into so many furcles as is the veyne. It runneth transuersly and inward along the commissure or ioyning together of the share-bones vnto the Priuities, and is consumed in the skin of the yard. Sometime also small arteries are sent vnto the glandules of the groyne: againe often from one side a reasonable branch is produced vnto the groine, which cheriseth not onely the skin about the share, but also those parts which pertaine or reach vnto the haunches or the *abdomen*. The remainder of the artery [ta. 17 char. 18] runneth into the Leg and maketh the *Cruall* arteries, of which we shall speake in the 20. Chapter. And thus much of the branches of the great Artery which accompany the hollow veine in the lower belly. Now we come vnto those that accompany the Gate veyne.

CAP. XVI.

Of the Arteries accompanying the branches of the Gate-veine through the lower Belly.

Celiaca.

THE Arteries which accompany the branches of the Gate-veine are three. The first is called *Celiaca* [tab. 18, fig. 1, m. table 17, char. 6,] the second *Mesenterica superior*, [tab. 17, char. 10,] the third *Mesenterica inferior*, [Tab. 17, char. 12,] the *Celiaca* [tab. 18, fig. 1, m. tab. 17, char. 6,] is so called because it sendeth many branches vnto the stomacke, and therefore we may call it the stomacke artery. It is a notable vessell and because like the gate-veine it offers his branches to the stomacke, the kell, the *Duodenum*, the beginning of the *Ieiunum*, a part of the collicke gut, to the Liuer, the bladder of gall, the *Pancreas* and the spleene, we will fit his names vnto the names of the gate-veine.

The division thereof.

It ariseth from the forepart of the body of the great artery at the spine of the backe. And the vpper part thereof is sustained in his course by the lower membrane of the *Omentum* or kell. Afterward it is diuided into two branches, a right [Tab. 18, fig. 1 u] which is the lesser; and a left [Tab. 18, fig. 1 u] which is somewhat greater. Both of them spring as it were out of one roote, and vnder the back-side of the stomacke are fastened to the gate-veine in the *Pancreas*.

The right [tab. 18, fig. 1 u] ascendeth vpward into the hollow part of the Liuer, hauing some part of his way sprinkled branches, some from his vpper part some from his lower. From his vpper part two.

Gastrica dextra.

The first is called *Gastrica dextra*, the right stomacke artery. [tab. 18, fig. 1 p] It issueth out of the middle of the passage and distributeth his furcles into the back-side of the right orifice of the stomacke.

Cystica gemella.

The second are two small twin-branches called *Cystica gemella*, [tab. 17, char. 8, tab. 18, fig. 1, fig. 2, x] because they go vnto the bladder of gall. From the lower branch issue three branches.

Epiplois dextra.

The first is called *Epiplois dextra* the right kell artery, [tab. 18, fig. 1 o fig. 2, b] and is offered to the right side of the lower kell, and to the collicke gut which is fastened thereto.

Intestinalis.

The second is called *Intestinalis* the gut artery, [tab. 18, fig. 1 q, fig. 2, d] and is sent vnto the *Duodenum* and the beginning of the *Ieiunum*.

Gastro-epiplois dextra.

The third is called *Gastro-Epiplois dextra*, the right stomacke and kell artery. [tab. 18, fig. 1, r,] It is larger then the former, and is retorted or bent backward to the right side of the bottome of the stomacke, and leaning vpon the vpper membrane of the kell, sprinkleth very plentifull furcles into the fore side and hindside of the bottome of the stomacke, as farre as vnto the middle thereof. That which remaineth of the right branch determineth into the hollow part of the Liuer, [tab. 17, char. 7 tab. 18, fig. 1, t, fig. 2, y] yet not deepe, to conuaye vnto it vitall spirit.

Arteria splenica.

The left branch [tab. 18, fig. 1 u] which is also called *Arteria splenica* the Artery of the spleene passeth with an oblique and crooked course through the *Pancreas* [tab. 18, fig. 2, e] vnto the spleene. [tab. 18, fig. 2, m] It is larger then the right branch that it might not easily be obstructed, for it doth not onely suggest into the Spleene plenty of vitall spirits, but also vomitteth out and purgeth into the same the thicker and more foeculent matter of the spirituous blood contained in the great Artery. It is fastened to the splenicke veine and is distributed like vnto it, for from it before the diuision there issue from the vpper part two Arteries, and as many from the lower.

His diuision.

Gastrica maior.

The first that issueth from the vpper part is called *Gastrica maior*, the greater stomacke Artery [tab. 18, fig. 1, x] which offereth to the stomacke a propagation in the backe and vpper part; wherefrom a furcle [tab. 18, fig. 1 y] runneth vnto the middest of the stomacke.

Coronaria stomachica.

Another also called *Coronaria stomachica*, the Crowne artery of the stomack, [tab. 18, fig. 1, ch. 2, fig. 2, g] which reacheth to the vpper orifice compassing it about like a crowne, and it alloweth small furcles to the body of the stomacke and to the gullet.

Gastrica sinistra.

The second is called *Gastrica sinistra*, the left stomacke artery. [tab. 18, fig. 2, a] It is a propagation of the former *Gastrica maior* running on the right hand into the vpper parts of the stomacke, and distributing furcles on both hands which attaine vnto the *Pylorus* or lower mouth of the stomacke.

Epiplois postica.

From the lower part of the left branch yssue likewise two arteries. The first is called *Epiplois postica*, [table 18, fig. 1, b fig. 2, e] the hinder kell-artery, which presently is diuided into

into two furdles separated farre one from another, and those into others which are propagated into the lower membrane of the kell and the collick-gut which is tyed thereto.

Table 18 is the same with Table 4. Lib. 3.

The second is called *Epipliois sinistra*, the left kell-artery. [Table 18, fig. 1.] It is also sent to the lower membrane of the kell and runneth out into his left side. That which remaineth of this branch [Table 18, fig. 1, u] attaineth to the spleene, and is divided into an vpper and a lower branch, and these againe are divided into others vntill many branches doe touch the hollow part of the spleene, [Table 18, fig. 1, s] and are dispersed through his substance.

Table 19 is the same with Table 7. Lib. 7.

Out of the lower part of this remainder issueth that artery which is called *Gastro-epiplois sinistra*, [Table 18, fig. 1, e] which is supported by the vpper membrane of the *Omentum*, writen toward the right hand that it might creepe vp the left part of the bottom of the stomacke, and sendeth crooked and bent branches to the fore side and back-side thereof, and to the vpper membrane of the kell.

Out of the vpper part of the remainder issueth that which is call *Vas breue arteriosum*, That short arteriall vessell, which is inserted into the vpper part of the left side of the bottom of the stomacke.

And this is the diuision of the *Celiacall* Artery in the lower belly which is the first of the three that accompany the branches of the Gate-veyne. The second and third are the two *Mesenterick* Arteries both which yssue from the fore side of the trunk, the vpper below the *Celiacall*, the lower below the *Spermaticall*.

The vpper *Mesentericall* artery [Table 17, char. 10, Table 18, fig. 1, 2, fig. 2, p] is propagated into the vpper part of the *Mesentery*, yea almost into all of it, and sprinkleth abundant furdles into the *Ieiunum*, the *Ilium*, and the *Collick* guts at the right kidney.

The lower *Mesentericall* artery, [Table 17, char. 12, Table 18, fig. 1, q] runneth vnder the lower side of the *mesentery* & is especially distributed into the left side of the collick and into the right gut, and descending together with the veynes vnto the fundament, maketh the *Hemorrhoidall* Arteries. [Table 18, fig. *]

The vse of these *Mesentericall* branches is not so much to conuay heat vnto the parts, as by their motion and vitall spirit to perferue the *Mesentery* and the guts from corruption and putrification.

Some are of opinion that these branches do sucke out of the guts the purest part of the chylus for the generation of arteriall blood and conuay it to the left ventricle of the heart: but the values which are set at the beginning of the great artery, and shutte vp the passage from the artery into the heart onely, and not out of it againe, do contradict strongly that conceite.

Hauiing thus brought the great artery through the middle and lower regions of the body, we will now returne vnto it againe, where we left it in the 14 chapter diuided into two *Soporary* Arteries and climbing vnto the Head.

CHAP. XVII.

Of the Arteries of the Braine.

HE artery called *Carotis* or the sleepey artery, and by *Archangelus* *Arteria Iugularis* because it is accompanied on the inside with the internall Iugular veyne, ascendeth vnto the chops on either hand by the sides of the rough artery, and there is diuided into two branches. One externall, of which we shal speake in the chapter following. Another internall, which is also the larger conuayed to the Chops, which hauiing afforded certaine furdles to the tongue and the *Larinx* is diuided at the basis of the braine [Table 19, fig. 13, B] into two vnequall branches.

The first artery of the braine according to *Bauhine*, according to *Vesalius* the 3, [Table 19, fig. 13, L. 15, c] is little lesser then the Trunke it selfe, & runneth vp whole & full til it come vnto a proper hole bored for it in the temple-bone, and through it attaineth into the cavity of the scull at the saddle of the wedge-bone, & being yet vnder the *Dura mater*, first of all it affordeth a branch on each hand into the side of the same *Meninx*. [Tab. 19, fig. 15, D] Afterward in brute beasts it parteth with an infinite number of furdles, and maketh that texture which is called *Rete mirabile*, the wonderfull Net: of which *Galen* wrote so curiously that *Vesalius* followeth him to a haire, and that figure is the 14 of this 19 Tab. but the 16 fig. of the same table exhibiteth the form thereof, as it appeareth in brute beasts, especially in oxen, calues, & sheepe.

In men though there be indeed such a knot or texture, yet it is not so notable, and but a very shadow in respect of that in brute beasts, and yet notwithstanding the Artery is not consumed into these propagations but remaineth alwaies sound. [Tab. 19, fig. 16, B c] Presently after it perforateth the *dura meninx* and runneth sometimes single, sometimes double, [ta. 19, fig. 15 P] yet so that it presently vniteth againe, and when it hath transmitted the lesser branch [K] through the second hole of the wedge-bone, it creepeth out of the scull vnto the eye and the temporall Muscle [table 19, fig. 11 H] together with the Opticke nerue to giue it and his Muscles life, and sendeth the greater branch vpward, which presently at the side of the Flegmaticke Glandule is diuided into two branches. The inner whereof is vnited with the inner artery of the opposite side, and so being vnited they are consumed into many smal arteries which at the originall of the optick nerues are disseminated through the *Pia Mater* and the substance of the Braine. [Table 19, fig. 13, e] The other being reflected [table 19, fig. 13, at the uppermost A fig. 15 G] and entangled in the *Pia Mater*, runneth into the forward ventricle diuided into many small branches, some of which are vnited with those small arteries which attained hither from the *Cervicalis* or artery of the necke through the basis of the Head vnder the Braine. Some others run disioyned through the *Pia mater* or thin membrane and through the substance of the Braine it selfe, which with other surcles make the complication of vessels which they call *Plexus Choroïdes*, so that this complication is compounded of foure arteries.

Plexus Choroïdes.

The 2 Artery.

The pulse of the Nose.

The 3 Artery of the Braine.

The fourth.

The use of the arteries of the Braine.

The second Artery of the Braine [ta. 19, fig. 13, q] is a branch of the former which runneth obliquely, and when it hath attained into the scull through the second hole of the Temple-bone, it is diuided into two branches; whereof one runneth outward and the other inward. The vter which *Vesalius* calleth the second small branch of the third artery [tab. 19, fig. 13 f] tendeth through the eyght hole of the Wedge-bone into the cavity of the Nosethrilles [Tab. 19, fig. 15 E] where the Pulse is felt, and offers a little surcle to the end of the Nose [tab. 19, fig. 13, t] but the interiour branch is diuided into two at the first Hand [tab. 19, fig. 13 uu] which *Vesalius* calleth two great branches of the third artery. Afterward it sendeth out of his vter part another small branch, [Table 19, fig. 1, r] which *Vesalius* calleth the first small branch of the third Artery; this branch together with the second Veine, [F] & after the same manner and for the same vse is distributed into the *dura meninx* or thicke Membrane.

The third Artery of the Braine which according to *Vesalius* and *Platerus* is the second, [tab. 19, fig. 13, l] is lesse then the first and runneth together with the branch of the internall Iugular veine [tab. 19, fig. 13, C] vnto the backside of the Scull, and hauing afforded a surcle vnto the Muscles which occupy the inside of the necke [e] it entreth in at the first hole of the Nowl-bone, and so passeth into the *sinus* of the *dura mater*.

The fourth Artery (which according to *Vesalius*, *Falopius* and *Platerus* is the first) is a propagation of that axillary artery being yet within the Chest which is called *Cervicalis*. This arising vpward through the holes of the transuerse proecesses of the neck, after it hath giuen some surcles to the muscles thereabout, betwixt the head and the first Racke of the necke it perforateth the thicke membrane which inuesteth the spinall marrow in the side thereof: to which after it hath giuen some propagations it entreth into the cavity of the Scull through the great hole. Afterward vnder the marrow it is ioyned with his companion of the opposite side, which being so vnited doe passe along vnder the middle of the basis of the Braine till it come vnto the saddle of the Wedgebone wherein the Phlegmaticke Glandule is contained. There againe it is diuided into two branches. The right runneth to the right side of the saddle, the left creepeth on his owne side as farre as to the second paire of sinewes, where on both hands it is diuided into infinite surcles and disseminated betwixt the first and second paire of sinewes, and complicated or intangled with the *Pia mater*, which complications afterward do make the *Plexus Choroïdes*. And thus much of the distribution of the arteries within the braine.

Moreover, we must imagine that frō these sleepey arteries an innumerable number of surcles or propagations are sprinkled heere and there throughout the whole substance of the Braine.

The Vse of the arteries of the Brain is to be considered either as they are Canales or pipes running through the Braine, or as they are perpetually mooued.

In the first consideration they were made to conuey vitall Blood from the Heart vnto the Braine, as also vitall spirits to sustaine the vitall spirits that are bred and seated in the substance thereof; neither do they carry vitall spirits onely, but also the vitall faculty furnished with all his indowments.

As

As they beat continually, their vse is perpetually to ventilate the ingent heat of the Braine, which otherwise would quickly languish and be extinguished. Again, this pulsation moueth and worketh the blood in the veynes, which if it stood still and at rest would like standing water sooner putrifie and corrupt. Finally, to sollicite the Alimentary blood which is thicker, to issue out of the veines through small pores and vents or breathing passages into the substance of the braine (which also doeth somewhat drawe it) for his nourishment and refection.

Now we proceed vnto the exterior branch of the Sleepy Artery.

CHAP. XVIII.

Of the Arteries of the Face, the Eyes, the Nose, the Teeth, and the Larynx.

THE Carotides or sleepy Arteries [Table 16, X R] being on both sides one, doe accompany the Iugular veines by the sides of the necke, and cleauing to the Rough artery ascend vnto the head, and when they come vnto the Chops they are deuided [Table 16, f f] into an vter branch [g] and an inner, [h] the distribution of the inner we had in the former Chapter.

The diuision of the sleepy artery.

The vter which is smaller then the inner and consisteth without the Choppes, lendeth surcles to the Cheeks [l] and to the muscles of the Face, afterward when it cometh vnto the roote of the Eare [m] it is deuided into twaine, one of which runneth to the back-side of the Eare, [o] from which two arteries vnder the Eare doe passe into the neather law, and throughout the length thereof are disperfed vnto the roots of all the lower teeth; another part of it breaking out through a hole at the Chiane runneth along the Lip; another yet [n] creepeth vp the Temples and the forehead, and is consumed into the muscles of the Face. Of the Arteries of the Eyes we haue spoken before in the former Chapter, as also of the Nose; of the Teeth a litte before, whence it is that we often find pulsing or beating paines in them, such as we feele in inflammations of fleshy parts, and this was Galens obseruation in the 8. chap, of his first Booke de compositione medicamentorum secundum loca, who found in himselfe not onely the paine of his Teeth, but also their beating or pulsation, wherefore he affirmeth confidently that there is one kinde of paine in the gums and another in the substance of the Tooth, and without the inflammation of the Gummes sometime in the proper body of the Tooth, sometimes in the Nerue paines doe perplex vs. And truly if there were no Artery at the roote of the Teeth, how could it be that when a Tooth is perforated, so much cleare and perfect blood should issue out from it? Which as Eustachius saith he obserued in a man who had so great a fluxe of blood from his tooth that almost powred out his life therewith.

Galens

That there are arteries in the teeth.

Eustachius his obseruation.

Finally, which we also partly remembred before, from the greater and inner bough of the sleepy artery which runneth vnder the Chops, some surcles are communicated to the throtle and Tongue to conuay vnto them life and heat: and thus much of the diuication of the Soporary or sleepy arteries both without the Scull and within: it remaineth that we should entreat of the Axillary and Crural arteries, as they are distributed into the ioynts, but we will begin with the Axillary.

CHAP. XIX.

Of the arteries of the Hand in the large acception.

THE great Artery after it is out of the Chest distributeth foure branches from each side of the Axillary; the first from the back-side to the Muscles situated vpon the shoulder blade; [table 10 fig. 2, I] another from aboue the ioynture of the Arme with the blade, which the Humerary veine accompanieth for a time: [K] the third to the Muscles that lye vpon the forepart of the Chest, [L] the fourth runneth downward along the sides of the Chest [M] and communicateth small branches to the glandules vnder the arme-pits betwixt the third branch and the fourth; of these we haue spoken before: the remainder is conuayed vnto the hand [from N.]

4. branches from the axillary.

For this branch [N] descending through the inside of the Arme together with the Basilica veine [table 20, fig. 1 m] betwixt the muscle called Biceps or the two headed muscle, distributeth small surcles on either side to the muscles which take vp the inside of the arme. [vnder M] Afterward being accompanied with the Deepe-veine [tab. 20, fig. 1, q] or the inner branch

Table 20. Figure 2. sheweth the branches of the great Artery, running thorough the whole hand.

TABVLA XX.

FIG. II.

FIG. II.

G, The Mammary artery fastened on the one side into the breast-bone.

H, The Artery of the necke, called *Cervicalis*, going to the backward muscles of the necke.

I, *Scapularis*, going to the muscles of the shoulder-blade.

K, The Artery climbing vnto the top of the shoulder.

L, *Thoracica superior*, going to the muscles that lie vpon the breast.

M, *Thoracica inferior*, creeping along the sides of the Chest.

N, The axillary artery attaining vnto the arme, and bestowing small branches vnto the muscles.

O, It attaineth to the outside of the cubite.

PP, Vnto the ioynt of the cubit.

†, The by-partition of the Artery vnder the bought of the Cubite.

Q, An vpper branch of the Artery carryed along the Wand.

R, A furcle going vnto the vtter sides of the hand, where wee vse to feele the pulse.

S, The lower branch of the artery running along the *Vlna*.

* A small branch to the muscles, about the little finger.

T, The distribution of the vpper and inner branches, into the hand and into the fingers.

of the *Basilica* (where to it is fastned in his whole course) as also with the fourth Nerue of the arme, it runneth through the backside into the outside of the cubit vnder the heads of the muscles thence arising, and shooteth forth small branches aboue and below [O] and neere the bent of the elbow it affoordeth on either side two branches to the ioynt [PP] where the pulse may be oftentimes evidently felt.

Galen.
The *Anastomosis* of the vessels.

We said that the Artery runneth with the veine, For it is certaine (saith *Galen* in the 10 and 17 chapters of his sixth Book *de vsu partium*) that in the whole body there is a mutual *Anastomosis* or *inoculation* between them, that is, their mouths open one into another, and so a *Conspiration* and *Communion* of their matters. For the arteries doe impart vnto the blood spirits and vitall heate, and for retribution the arteries draw out of the veines blood which is the nourishment not onely of their spirits but of the arteries themselves; and these coniunctions of the vessels made by their orifices or mouths are found especially in the armes and the legges, and therefore it hapneth sometimes that one only veine being wounded, not onely all the naturall blood of the body but together with it the vitall also issueth, and so the wounded man perisheth. And this *Galen* also intimateth; for going about to demonstrate the vnions of the vessels, he saith, that if the greater veynes be wounded, if the blood be suffered to flow forth, the Arteries also will be euacuated by consequence: and this appeareth true by experience. For if you open a man that dieth of bleeding, you shall finde not onely the veynes but the arteries also empty. But I returne from whence I haue digressed.

Galen.
The axillary Arteries descent.

The Axillary Artery vnder the bent of the Cubit when it hath run a little way thorough the inside of the Cubit, descendeth into two bending muscles of the fingers, and is diuided into two notable branches, *Columbus* addeth oftentimes into three. The one is the vpper and passeth along the *Radius* or wand [Q] till it come in a straight line vnto the wrest, at which place the Physitians commonly feele the pulse, making estimation of the disposition of the heart from the Dilatation, Contractiō, and intermediat Rest of the artery. but, this is not alwayes seated in the inside of the wrest, but runneth sometimes outward, so that if a Physitian be ignorant of Anatomy, and search for the sicke mans pulse only in the usuall place which is in the inside of the wrest a little about the roore of the thumbe, not finding it, he will determine that the Patient is neere his death, when haply the artery beatech well on the vpper side against that place.

The pulse in the wrest. Note this.

Before the artery of the pulse get vnto the fingers it sendeth a shoote toward the out-side of the hand [Table 20, R] betwixt the first bone of the thumbe and that of the afterwrest where-by the fore-finger is supported, and distributeth it into the muscles of that place. Afterward it goeth vnder the Annular or transuerse ligament, and the tendon of the muscle of the Palme (as also do the veyne and the nerue fastened thereto) and is diuided into three branches. The first of these offers two furcles to the inside of the thumb, the second to the inside of the fore-finger, the third is vadiuided and attaineth to the middle finger, [Table 20, between R and T.]

Three branches to the fingers.

The other and inferior branch (of which *Columbus* maketh no mention) [Table 20, S] runneth directly along the *Vlna* or *El*, and attaineth likewise to the wrest, at which place also we may feele the pulse to beate, especially if the party be leane, or haue a great pulse, and this is the reason why we rather touch the other artery then this, for the other is lesse covered by the tendons and offereth it selfe more manifestly that we may giue the better iudgment by it.

The lower branch of the Artery.

This branch also runneth vnder the fore-side transuerse ligament into the palme of the hand, and before it reach vnto the fingers affoordeth a small branch [Table 20, *] to the muscles that are seated neere the little finger. The remainder accompanied with a veine and an artery is communicated to the fingers: the middle finger hath one furcle, the ring-finger and the little finger each of them two. The outside of the hand as it wanteth muscles so it wanteth arteries also, vnlesse it be that branch which is marked with R. And thus much of the Arteries of the Hand.

His diuision.

CHAP. XX.

Of the Arteries of the Foot in the large Acception.

Whe said before that the great Artery about the lower spondels or rack-bones of the Loynes, or aboue the beginning of the *Os sacrum* or holy-bone, is diuided into two notable Iliacke branches. [Table 21, v.] Each of these is againe subdiuided on either side into two others, one exterior the other interior. [Table 21, § 1.]

The diuision of the Iliacke Arteries.

The interior [§ and Table 17, §] shooteth out two scions, one externall [o and table 17, §] called *Muscula inferior*, the lower Muscle artery which runneth ouerthwart and is consumed into the muscles that couer the outside of the haunch-bones and the ioynt of the hip: the other internall, [o and table 17, u.] called *Hypogastrica*, which runneth directly downeward and sendeth his furcles to the parts of the *Hypogastrium* or *Water-course*, as the bladder, the womb, &c. The remainder of this branch [Table 21, §] descending [vnder s] first admitteth the vmbilicall artery of his owne side; after it assumeth a portion from the outward branch of the first diuision [neere o;] and so increased it passeth through the hole of the share bone into the leg, and is distributed into the muscles which occupy the share-bone; thirdly in the end it ioyneth [table 21, §] with another artery. [4.] The vtter branch or the stocke it selfe running downeward accompanied with his veine whilest it is yet in the belly [aboue o] sendeth one branch vpward and outward through the cavity of the *Abdomen* called *Epigastrica* [table 21, §, table 27, char. 22.] vnto the muscles thereof, and another inward called *Pudenda* [table 21, §, table 17, char. 15,] which issueth from the Artery sometime within the *Peritoneum* sometimes without, and runneth along the share-bone; but of these we haue spoken before in the 15 chapter, and repeated them briefly heere to make better way vnto that which followeth.

The Iliacke trunk of the great artery when it hath passed through the *Peritoneum* and the cavity of the belly in the thigh, is called *Cruralis*. [table 21, §, table 17, char. 16,] and from it branches on either side are propagated and disseminated into the whole foot, eight in number.

The first is called *Muscula Cruralis exterior*, the vtter crurall muscle Artery. [table 21, §.] It issueth out of the outside of the crurall trunk, and running downeward is consumed into the foure muscles that compasse that bone of the thigh.

Mus. Cr. ext.

The second is called *Muscula cruralis interna*, [table 21, §] because it riseth out of the inside

Mus. Cr. inter.

Table 21. Sheweth the distribution of the great Artery into both the feet.

toes themselves, betwixt the tendons of their muscles. *a, b*, the diuision of the branch ω into 5 to the great toe, fore-toe, and the middle toe. *d*, the diuision of the exterior branch vnto the middle toe, and the next vnto it.

side of the aforesaid trunk sometime answering in opposition to the former, and is distributed into the muscles which occupy the inside of the thigh, and falling downe vnto the knee, a small branch thereof is mixed ω with the last branch of the *Hypogastricke* artery.

Poplitea.

The third is called *Poplitea*, [tab. 11, T] the crural trunk creeping downward vnder the hamme, being accompanied with a large veine, maketh this propagation: some surcles thereof runne out into the backward muscles of the thigh, the rest descendeth a good way to the hamme-veine.

Suralis.

The fourth is called *Suralis*, the trunk lurking in the hamme or a little vnder it, shooteth out on each side a deepe propagation, [tab. 21, $\Delta\Delta$] which are consumed, partly in the ioynt of the knee, partly into three muscles of the foot which make the Calfe, & take their originall thereabouts. And these are the foure arteries which arise from the trunk in the region of the thigh, from hence it descendeth to the hamme [tab. 21, Θ] together with the interior veine, partly to the leg, and partly to the foot; when it is drenched within the muscles of the leg it is diuided into three notable branches, [tab. 21, $\Lambda\Sigma\Pi$].

Tibia exterior.

The first which is the first of these three [Δ] is called *Tibia exterior*, the outward leg artery. It is a notable branch of the vter veine, and so descendeth along the Fibula or Brace, and is consumed into the muscles which occupy the leg as farre as they are fleshy.

The

a, The lower mesentericall artery.

mm, *Lumbares* which runne in knots or knees into the spondels of the loynes.

rr, The diuision of the great artery into Iliacke branches about the holy bone.

ξ , the diuision of the right Iliack into an inner branch at ξ , and an vter at σ .

o, *Muscula inferior*, an vter propagation of the inner branch going into the muscles covering the ioynt of the Coxendex.

n, *Hypogastrica*, an inner propagation of the inner branch at ξ , going to the bladder, the yard, and the wombe, &c.

$\rho\sigma$, the coniunction at σ , of the vmbilicall veine ρ , with the branch ξ .

xx, *Epigastrica*, which is sent vpward into the right muscles of the *Abdomen*.

u, *Pudenda*, which creepeth transfuersly along the share-bone vnto the priuities.

ϕ , the externall Iliacke branch.

χ , the outward crural *Muscle-Artery*.

ψ , the internall crural *Muscle-Artery*, which is sent to the muscles of the thigh on the inside.

ω , the coniunction of this Artery with a branch of the *Epigastricke*.

I, *Poplitea*, or the artery of the hamme.

$\Delta\Delta$, propagations of the surall Artery on either side going vnto the ioynt of the knee, and three muscles of the foot.

Θ , *Suralis*, the artery of the Calfe which descendeth with the inner veine, and is diuided into three branches, $\Lambda\Sigma\Pi$.

Δ , *Tibia exterior*, going vnto the muscles of the foot.

$\Pi\phi$, the lower and backer *Tibia*, hidden within the muscles, attaineth vnder the transfuers ligament to the vpper part of the foot at ϕ , and is consumed into the muscles of the toes.

$\Sigma\psi$, the lower, the trunk of the crural artery betwixt the heele and the inner artery, to which it offereth a branch marked with ψ , which runneth to the vpper side of the foot.

Ω , the remainder of the Crural artery going to the

toes themselves, betwixt the tendons of their muscles. *a, b*, the diuision of the branch ω into 5 to the great toe, fore-toe, and the middle toe. *d*, the diuision of the exterior branch vnto the middle toe, and the next vnto it.

The sixt *Cruall* Artery is the second of the forenamed branches [table. 21, 2] and is called *Tibiaa posterior elatior*, the vpper and backer Leg artery. It yflueth a little below the former out of the backer and lower part of the trunk, and descendeth as far as to the commixtion of the tendons of the muscles that make the Calse, being accompanied with the hinder branch of the *interior* veine.

The seauenth which is the third and last of the foresaid branch [Table, 21, 11] is called *Tibiaa posterior et humilior*, the lower and backer Leg Artery. It ariseth out of the backward and exterior part of the trunk, and being accompanycd through the membranous Ligament (with the fore-branch of the inner veine) which ioyneth the *Brace* vnto the *Leg*, it is hidde within the muscles, and runneth forward and downward further then the other two till it passe the transuerse Ligament and attaine to the top of the foote, [Table 21, q] from whence it is disseminated into the muscles that leade the Toes backward, at which place *Vesalius* and *Platerus* say that the pulse may be easily felt.

The eight Artery of the Leg is nothing else but the remainder of the *Cruall* trunk descending along the backside of the *Tibia* or Leg, [table 21, the lower 3] betwixt the 2. and 3. muscles of the Toes, and so it passeth betwixt the heele and the inner ankle vnto the soale of the foot, but at the inner ankle it offers a branch to the foote, [table 31, 4] which reacheth to the muscle of the great Toe, and creepeth a good way vpon the top of the foote.

That which is left [Table 21, a] amongst the tendons of the muscles of the Toes, is deuided into two branches [a b] each of which departeth into 5. surcles: for the inner branch [c] affordeth two to the great Toe, two to that next it, and one to the middle. The exterior [b] offereth two to the little Toe, two to that next it, and one to the middle Toe [d] and the lower side thereof.

And thus much concerning the distribution of the great Artery throughout the whole body. It remaineth that we come vnto the third sort of vessells which are the nerves, for whose prosecution we haue set aside the third part of this Booke.

The third part of the Eleauenth Booke

concerning the Nerves.

CHAP. XXI.

Of the Nerves in Generall.

AS the Naturall Faculty together with the Bloud and the thicker Spirit is deriued through the Veines; the vitall with Bloud and a thinner Spirit through the Arteries as through Canales and Water-courses into all the parts of the body: so the Animall Faculties, that is, of *Sense* and *Motion* are conuayed into those parts which are capable thereof with a subtle and fine Spirit along by the Nerves as it were by the strings of an Instrument.

The Natures, Vses and Diuisions of the Veynes and Arteries we haue vnfolded in the two former parts of this Booke, and are come in this place to the structure, differences and diuarcations of the Nerves.

The Grecians call Nerves *νεῦρα*, the acception of which words among the Philistians is manifold. *Erotianus* thinketh that *Hippocrates* vsed the word *νεῦρα* for all sortes of vessells, Veines, Arteries and Nerves. *Galen* in his first Booke *de motu musculorum*, in the beginning of his Booke *de ossibus* and in many other places, maketh three kinds of Nerves which appeare without blood and without any hollownesse.

Of these Nerves some proceed out of Bones, others out of Muscles, others are deriued from the Braine and the spinall Marrow. Those which issue out of the Bones and their protuberations are called *σύνδεσμοι*, *Vincula*, Tyes, Bands or Ligaments. Of these we shall heare particularly in the next Booke. Those Nerves that issue out of Muscles are parts of the Muscles, and are called *ἀπὸ τῶν ὀστέων*, that is, nervous propagations and Tendons.

Now a Tendon is nothing else but an excreffence or out-growing of the Fibres of a Ligament and a Nerue, which being sprinkled through the flesh doe meete together as it were in one Chord, by which chord the Ioynts are ledde according to the good pleasure

Tibiaa posterior elatior

Tibiaa posterior et humilior

What the eight artery is;

The names of Nerves and their kinds.

sure of our will. The third kind of Nerves are those which the Physitians doe properly call *νεύρα ἐκ τῶν ὀστέων*, and that from their office; *νεύρα*, because they doe *nutare sine flectere*, that is, incline or bend, and *τῶν ὀστέων*, because they doe *Tendere*, that is, stretch. These Nerves doe arise from the Braine and the spinall Marrow, and are called by *Galen*, *organa ὑποκείμενα*, Instruments of Sense and voluntary Motion, because by them the animall Faculty, and those that moue within, that is, the impetuous spirits, are conuayed as it were by strings or chords into the particular parts. *Anicen* calls them *Latores*, cadgers in our language. Of these *Hippocrates* wrote in his booke, *De locis in homine*, The whole body is full of Nerves, that is, throughout the whole body the Nerves doe run from the Braine and the Spinall Marrow: and in his Booke, *De arte*, he calleth them *metecors* in the flesh, because they are sprinkled through the flesh, that is, through the Muscles.

Compared together.

Galen in his first Booke, *de motu Musculorum*, compareth these three kinde of Nerves among themselves on this manner, A Ligament is insensible, a voluntary Nerve of most exquisite Sense, and a Tendon of a middle nature, not altogether insensible, because it hath some filaments or strings of Nerves therein, neither yet of so quicke a Sense as is a Nerve.

There are also many other parts in the body, which because of the similitude betwixt them and Nerves are called *neruosi*, although they cannot be referred to any of these three kinds: so we say the wombe, the bladder and the guts are neruosi, as also the vreters, the passages of the choller, and the eiulatory vessels. In this place we take the name of a Nerve properly for an organ by which the animall spirit and the faculty floweth into the whole body. The nature of this Organ may thus be described.

The description of a nerve.

It is a common Instrument of the body like a Chord, white, round and long without any cavity, which our sense can discerne (vlesse it be the Opticks) but porous, in some vnited, in the greater Nerves made vp of many small strings, and carrying as a Canale sense and Motion which are conducted by the animall spirit from the Braine and the Marrow thereof vnto those parts of the body which are capable of Sense and Motion.

Their substance.

Their substance is white and marrowy, much like the marrow of the Braine, from which they take their originall (for I account the marrow of the Braine and the backe to bee of one and the same substance) but more compact and faster, for it was necessary the Braine should be very soft, because it was to receiue the species or formes of sensible things. So that by how much the Nerve descendeth lower, or is more separated frō the Braine, by so much doth it become the harder, that it might be better able to endure outward iniuries.

Membranes.

They are inuested with a double membrane, produced from the two Meninges or Membranes of the Braine, the vtter whereof is the thicker produced from the *dura mater*, whose office is to safegard and defend the marrow of the Nerve, and if it consist of many small chords or threds, it ioyneth them altogether, and when it hath encompassed them about, it receiueh into it branches from the neighbour-veines.

Fernelius

The inner membrane is thinner by much, and lyeth next vnto the marrow or substance of the Nerve. It ariseth from the *pia Mater*, and hath the exquisite sense of touching, which saith *Fernelius*, it communicateth to the parts whereinto the nerve is inserted; for as the Braine is couered with these two membranes, so also are the Nerves throughout the whole body, a Nerve being nothing else indeed but a production of the Braine. But this threefold substance of a Nerve, as *Falopinus* hath it in his obseruations, and out of him *Bauhine*, may better be distinguished by reason, then by sense, for Anatomy is not able to shew the difference betwixt the hard and soft membranes of any Nerve, except it be the opticks.

Which is their chiefe part.

The substance which is in the middest, or in the center of the Nerve, is the principall part thereof and performeth the action; for the sensatiue and motiue faculty is conuayed from the Braine vnto the parts, not by the coates but by the marrow. Hence it is, saith *Galen*, that if you cut asunder the marrow of a Nerve, presently the part into which that Nerve is inserted, is deprived of sense and motion; as for the membranes they doe the same office vnto the Nerve which they did to the Braine, for the Nerves are not properly the instruments of sense and motion (for the immediate organ of motion is a Muscle) but they are like pipes by which the whole sensatiue soule and the faculties thereof both sense and motion are led by the guidance of the animall spirit of the Braine vnto the parts of the body as they stand in neede either of sense and motion, and therefore the Physitians doe vse to call them the organs of sense and motion. For they communicate

vnto

vnto those parts into which they are inserted, either sense alone, or onely motion, or both together, for no part hath sense or voluntary motion without a nerve; and if the nerve that belongeth to any part be compressed, or intercepted, or cut asunder, or corrupted, the sense and motion of that part doth suddenly perish.

How a Nerve is the Organ of Sense.

Hence it is (as Aristotle also remembreth in his third Booke *De Historia Animalum*) that no part of the body hath any stupor or dulnesse, any palsee or resolution, any spasme or convulsion that hath not a Nerve in it. Now stupor is a diminution of sense, the palsee a privation of sense and motion, and a convulsion is a motion involuntary against our wils, and a depravation of that faculty.

Galen in the third and fift Chapters of his sixteenth Booke *De usu partium* saith, that those nerves which were made for voluntary motion are hard, and those that were made for sense are soft: and that the soft Nerves doe make for sensation and the hard for motion, nay he goeth further in the eight Chapter of his seventh booke *De Administrationibus Anatom.* and affirmeth that the soft Nerves are onely fit for sense but unfit for motion. Some againe conceive and not without great reason that the softnesse or hardnesse of a Nerve is diversly occasioned, first from the substance whereout they issue, and so the first Nerves which are said to arise out of the Braine are the softest, those harder that arise from the Spinal marrow, and those hardest of all which arise from the marrow contained in the racke-bones of the Loynes and the Holy-bone: Secondly, in respect of their production, so those Nerves are soft which run but a little way, as as if their journey be not out of the skull, whereas those that are led further off as vnto the muscles, are harder then they were at their originall.

The reason of the softnesse or hardnesse of a Nerve.

In like manner those that run anfractuouly, that is, with turnings and windings are very hard, as a branch of the third paire of the Braine. Again, those are hard which passe thorough a hard body, as that surcle of the fift coniugation which creepeth through the hole of the Temple-bone which the ancients called *Cacum* or the blind-hole, is made harder by the contact of the bone then his beginning was. Galen attributeth the cause of hardnesse and softnesse to the counsell of Nature, because, saith he, the instrument of Sense needed a soft Nerve as a Canale to leade along the Animall and sensative spirit, and a soft Nerve, because it was to be affected and to suffer somewhat from the sensible object, applying vnto it from without.

Galen's opinion.

Now, because that which is soft is fitter for passion, that which is hard for action, therefore, saith he, it was necessary that the instruments of the senses should haue soft Nerves communicated vnto them, and the parts which were to be moved by voluntary motion should haue harder Nerves. And this he proueth, because vnto those Instruments of sense which haue not onely sensation but motion, there is a double kind of Nerve communicated, one for Sense, another for Motion; as we see in the eye vnto which the first coniugation is allowed for Sense and the second for Motion; so in the tongue, which receiveth the third and fourth coniugations (so Anatomists doe vsually distinguish them) for Tasting and the seventh for Motion.

By the way hence it appeareth, that Nerves beside their vse haue also an animall action, because they are affected by the object, and therefore the softer Nerves are fitter for sense and the harder for motion. Notwithstanding all this saith *Banbina*, yet we conceive that the Nerves of their owne nature are indifferently disposed both to sense and to motion, so that they may be called *Sentientes* or *Motores*, perceivers or movers from the instruments or parts vnto which they are conducted and in which they are disseminated, for if they bee inserted into the instruments of motion, that is, into the muscles, then are they called *Motory* or moving Nerves: If into the instruments of Sense, then are they called *Sensory* or perceiving Nerves; yea, we see that one and the same Nerve doth convey motion and sense according to the diversity of the instruments; for example, the seventh Coniugation of the Braine, conveyeth vnto the Membranes of the bowels which are in the middle and lower belly, the Sense of touching, and yet the same paire being on either side reflected makes the Recurrent Nerve which distributeth surcles into every muscle of the Larinx or Throate to moue the same. And if the same Nerves should meet with the instruments of Seeing, of Hearing and of Tasting, the same perceiving and moving Nerves would also become Seeing, Hearing and Tasting Nerves.

Banbina's opinion. His reasons.

An instance.

In like manner the Nerves which are conveyed to the muscles to afford vnto them voluntary Motion, doe altogether with that power afford vnto the Membranes of the muscles

cles, into which their fibres doe determine, the sense of Touching, and so it commeth to passe that by the mediation of the Nerves, the Braine is to be found in every part of the body, because the animall faculty which is seated onely in the Braine, doth notwithstanding transfuse it selfe through the Nerves.

The uses of the Nerves.

Although out of that which hath been said, we may easily collect the use of the Nerves, yet it shall not be amisse to remember that *Galen* in the ninth chapter of his fift booke, *De usu partium*, and out of him *Vesalius* in the first chapter of his fourth booke, makes a three fold use of them.

The first to convey sense vnto the instruments of sensation, to the eyes, to the tongue, to the eares, and besides these to the palmes of the hands, and the insides of the fingers, yea, to the vppermost mouth of the stomacke also, for these after a sence are organs of sensation. For the best iudge by touching is the hand, and the mouth of the stomacke hath an exquisite sense of the want of aliment, which we commonly call *Hunger*.

The second use is to afford motion to the moveable parts, so the muscles which are the instruments of voluntary motion have Nerves conveyed vnto them, and because they were made to move the whole members therefore their Nerves are great and large, and because the same muscles stood in need of the faculty of discerning Tactile qualities for the security and preservation of our lives, therefore also they had Nerves, by which Nerves they have this faculty of sensation.

The third use is that for which all other parts have Nerves, to wit, that they might perceive those things which would be grievous vnto them: (although this use may well be referred to the former) for so wise, so iust, so skilfull is Nature, saith *Hippocrates* (we say the great God of Nature) and so provident for the behoofe of the creatures, that shee hath distributed Nerves to all the parts, although not in the same measure, but to some more liberally then to other with a straiter hand, and that according to the proportion of their magnitude, of the dignity of their actions, of the intention or remission of their motions, of the assiduity or intermission of their uses. So making an exquisite estimate of the need of the dignity, and of the use of every part, to some she hath allowed greater Nerves, to some lesser, but to every one that is fittest for it.

The magnitude of nerves.

For there is great difference betwixt the magnitude of Nerves; the thickest are those which are distributed vnto the remotest places, and into the most parts, such are they that are sent vnto the ioynts, which because they needed greater abundance of spirits have a greater proportion of originals of sinewes granted them out of the stocke of the spinall marrow which is in the racke-bones of the necke and of the loynes, that from the marrow they might receive a competency of spirits as it were by many rootes, which yet being gathered together doe make one thicke nerve, but are againe though almost insensibly distributed into lesser branches. Those Nerves are Meane which are conveyed to the organs of the senses in the head: for being neare vnto the Braine and very soft, they could not be very small. Those nerves are small which are distributed into the next parts, as into the muscles of the face. Wee will also say something concerning the originall of Nerves.

Their originall.

The originall of the Nerves is not from the heart, though *Aristotle* so conceived in the fift chapter of his third booke, *De historia Animalium*, and in the fourth of his third, *De partibus Animalium*; for in dissection we meet with no Nerve produced therefrom, and those that are led vnto it from the sixt coniugation of the Braine are so small, that *Vesalius* witnesseth that he could find but one, and that with great difficulty.

Neither have they their originall, as *Erasistratus* thought in his youth, out of the *Dura mater*, or thicke membrane of the Braine, as their substance already declared, doth sufficiently witness. But as *Hippocrates*, *Erasistratus*, when he was wiser, *Herophilus*, *Galen*, and most Anatomists doe agree, from the Braine, from which also the spinall marrow draweth his originall. From the Braine I say, which is manifested as well by sense in the dissection thereof, where we see many rivers of Nerves, to which those of the body are continued: as also because their substances are marrowy alike, and cloathed each of them with two membranes.

Moreover, the affects or diseases of the head doe manifestly prove that all sense and motion doe flow from the Braine. So in the Apoplexy which is caused by an obstruction of the passages of the Braine, the Animall Faculty is instantly intercepted, albeit the heart be altogether indemnified. So in the Epilepsie or Falling sicknesse, where the mar-

row of the braine from whence the nerves do issue is affected, the whole body is drawn into Convulsion, which is nothing so when the heart is affected.

But we said before that a beginning is double, one of generation another of Dispensation. In respect of the Generation their beginning is Seede, of which as of their immediate matter they are framed. In respect of their Dispensation their beginning is in the braine, together I meane with the After-braine, which is the originall *à quo* from which, those Pipes (if so you list to call them) which receiue Sense and Motion are distributed into the body, as the part standeth in need of the one, or the other, or both.

Againe, the Nerves are said to be of two sorts, some proceeding from the braine, some from the Spinall marrow, and of these againe some from the beginning of the Spinall marrow, that is, being yet contained in the scull, others from the Spinall marrow which is in the Rack-bones of the Chinne. Againe, of these some belong to the marrow of the Necke, some of the Chest, some of the Loynes, and some of the *Os sacrum* or Holy-bone, to which also we may adioyne the nerves of the Loynes.

Bauhine in this place interposeth his owne opinion, which is, that all Nerves doe issue from the marrow of the braine oblongated or lengthned out, some whilst it remaineth yet in the Scull and some after. But withall he maketh mention of diuers opinions both of the Ancient and late Writers concerning the originall of the Nerves, which discourse of his we will here transcribe but contract it as briefly as we can. He reckoneth therefore eight opinions, for the ninth we thinke not worthy to be remembred.

The first is of *Hippocrates* in his book *de natura ossium* in the very beginning, where he saith that the originall of the nerves is from the Nowle unto the Spine, the Hippe, the Share, the Thighes, the Armes, the Legs and the Foote.

The second is *Aristotles*, who in many places deliuereth that they arise from the heart, because in it there are abundance of nerves (for which he mistooke the fibres) and because from thence motions do arise, & vnder his Ensigne *Alexander*, *Auicen* and the whole schoole of the *Peripateticks* doe merit or band themselves. This opinion of *Aristotles*, *Auerrhoes* and *Aponensis* with some others doe maintaine indeed, but with a distinction, affirming that they issue from the heart, *mediante cerebro*, by the mediation of the braine, or that they arise from the heart and are multiplyed and propagated in the braine.

The third is that of *Praxagoras*, who thought that the Nerves were nothing else but extenuated Arteries.

The fourth of *Erasistratus*, who thought they issued from the *Dura meninx*, but in his age he changed his mind as *Galen* witnesseth of him.

The fifth is *Galen*, who determineth that the Nerves and the Spinall marrow do proceede from the braine.

The sixth is that of *Vesalius*, who saith that some Nerves issue out of the Scull, others out of the Racks of the Spine; those that proceede out of the Scull doe arise from the basis of the forepart of the braine or from the beginning of the Spinall Marrow before it enter into the spondels. The rest from the Spinall marrow remaining within the Rackbones.

The seventh is *Ealopius* his opinion in his obseruations where he saith, that some Nerves (as those that are soft) doe arise from the braine or the marrow within the Scull, others from the Spinall marrow.

The eight is *Varolius* opinion, who saith that all Nerves doe take their originall from the Spinall marrow which proceedeth from the braine and the After-braine, and with him doe *Platerus*, *Archangelus* and *Laurentius* vpon the matter consent, as also doth *Bauhine* as you haue heard before.

The Nerves therefore which issue from the Marrow of the Braine contained yet within the Scull are commonly accounted 7 paires according to *Galen*, some make nine coniugations which are called *Nervi cerebri*. The nerves of the Braine, which may bee expressed in this disticke.

Optica prima, oculos mouet altera, tertia gustat

Quartaque quinta audit, vaga sexta, septima lingua est.

The Opticks first, Eye Mouers next, the third and fourth doe Tast:

The fifth doth Heare, the sixth doth gad, the Tongue claimes seventh and last.

To which also we may adde the organs of Smelling.

Other Nerves do arise from the same marrow after it is false through the great hole of

20 paire of the
spinal mar-
row.

the Nowle-bone, and runneth thorough the holes bored in the Racke-bones of the spine, where it is properly called *Spinalis medulla*, the *Spinal Marrow*. And these are thirty paires or Coniugations, that is to say; seven of the Necke, of the Chest or Backe twelue, five of the Loynes, and sixe of the Holy-bone, from which the nerves of the ioynts doe arise. For the hand receiveth sometimes five, sometimes sixe propagations from the fift, sixt & seventh paires of the Necke, and from the first and second paires of the Chest: the foot receiveth foure Nerves from the three lower paires of the Loynes; and from the foure, sometimes the five vpper-most of the Holy-bone, which are called nerves of the spinal marrow.

These nerves doe issue on either side after the same manner, for no nerve is produced without his companion, and therefore the *Grecians* called them *αὐζύσια*, the *Latines* *Nervorum paria*, or *Coniugia*, paires or coniugations of nerves. All these coniugations, as they doe arise alike, one from the right hand, the other from the left; so are they also distributed after one and the same manner, except onely the sixt paire of the Braine, whose right nerve is not divided as is the left, as we shall heare afterward.

And thus much shall have been sufficient to have said in generall, concerning the nature, differences, use, and originall of the nerves. Now we descend vnto their particular History, beginning with those of the Braine, because thence all nerves take their originall.

CHAP. XXII.

Of the Nerves of the Eyes, or of the first and second Coniugations.

The Mamil-
lary processes.

These two processes of the Braine, called *Mammillares*, which are the instruments of Smelling, doe come to be handled in the first place, but because we have related their History and exhibited the table which belongeth to them in the sixteenth chapter of the seventh booke, we will referre the Reader for his satisfaction vnto that place, and proceed vnto the nerves of the Eyes, whereof indeed we made some mention before, but that briefly, and by the way, as also we have done of the rest of the nerves, because they tooke their originall from the diuers parts of the substance of the braine, which was then the maine substance of our discourse.

The nerves therefore of the eyes are of two sorts: the first are called *Opticks* or *nervi visorij*, because by them we See. The second are called *Oculorum motorij*, the mooving nerves of the eyes, for by them the eyes are wonderfully and sodainly moued.

The Opticks
Nerves.

The Opticks are the first Coniugation of the Nerves of the Braine [tab. 22. fig. 1. and 2. G] which are the thickest of all the Coniugations of the Braine, yea, of all the rest, if they bee not compounded of diuers filaments. And so much the thicker they were, because, saith *Galen*, in the third chapter of his sixteene booke, *De usu partium*, they have sensible cavities, besides of all the other they are the softest.

Their origi-
nall.

They arise vnder the middle of the basis of the Braine, where the marrow beginneth to be lengthened. *Galen* in the third Chapter of his sixteenth booke, *De usu partium*, saith, they arise from both sides of the forward ventricles, to whose ends they are ioyned. Howsoever after their originall they run obliquely togetherward and forward, and when they have gone a little distance, and as it were in the middest of their iourney, they are vnited about the saddle of the Wedge-bone [Tab. 22. fig. 1. H.] not onely by intersection or simple contaction, but by a confusion of their marrowes, being so mingled as they make one common body wherein the two nerves cannot be separated one from another. Presently after this confusion they are againe separated [Table 22. figure 1. above H.] running each of them obliquely outward by a hole of the Wedge-bone, which was made of purpose, commonly accounted for the first hole of the same, and so getting out of the Scull, the right runnes vnto the center of the right eye on the hinder part, and the left vnto the center of the left, as if they were the rootes of the eyes. Notwithstanding *Vesalius* and *Platerus*, doe not thinke that their implantation is into the center, but to the right side ward. In brute beasts indeed they are not implanted into the center, but much lower, for they looke not so much forward as sideward. These Nerves are not dissolued into Fibres as other nerves are, but are spread abroad within the eye, notwithstanding *Vesalius* saith, that he hath obserued them in Swine to consist of many Filaments, as doe the Nerves of the Legges.

Their confu-
sion.

Separation.

The

The substance of the Opticke Nerue is double, Marrowy and Membranous, for the inner part is soft, which you shall perceiue will squeeze out if you presse the nerue hard whilest it is yet compassed with his membranes.

Their substance.

Of this Marrowy substance diffused in the Orbe of the eye, is made that coate which is called *Amphiblestroides*, or *Retina tunica*, from the resemblance it hath with a Net; [tab. 22. fig. 1. and 2. 1.] which notwithstanding, to say truth, is nothing lesse then a coate, because it differeth nothing at all from the substance of the braine, compassing the vitrious humour round about, and the middle part of the eye, that so the visive spirits might be diffused through the cavity thereof.

Retina tunica.

The membranes of the Opticke Nerves are two: one from the *Pia mater*, and another from the *Dura mater*, notwithstanding from their originall to the hole which is in the Orb of the Eye, and wherethrough they passe they are inuested onely with the *Pia mater*, from thence to the eye it selfe they assume another inuolution or vestment from the *Dura Meninx*, which also is consumed into the horny coate, as the membrane they haue from the *Pia mater* is spent into the grapie. Hence it is that by the continuation of this Nerue in a very moment of time the Animall spirit is conuayed vnto the *Pupilla*, or apple of the Eye, which is nothing else but the perforation or hole of the grapy coate. And therefore when one eye is shut we may easily discerne that the *Pupilla* of the other will be suddenly dilated, because of the affluence of the spirits. And by this demonstration *Galen* in the fourth Chapter of his seventh booke *De placitis*, maketh it manifest euen to the very sense, that there is not onely a spirit, but an Animall spirit in the body of man.

Their membranes.

If it be demanded why Nature did so prouide, that when one eye is shut, the spirits should all accrew to the other: I answer, it was to accomplish the perfection of that sense; for the concurrence of spirits doe better receiue the impression of the obiect and conuay it to the sense with more speed and certainty.

Concerning the counsell of Nature in vniting the Opticke Nerves, many men haue disputed diuersly. *Galen* thought it was, that one obiect might not appeare double, which conceite *Vesalius* dislikes, and so doth *Archangelus*, who addeth, that if that had beene the reason, the Nerves of Hearing, of Smelling, and of the rest of the Senses should haue beene vnited in the middle of their iourney, that one audible or odorable thing might not appeare double.

Diuers reasons why the optickes are vnited. Answered.

The second reason giuen for the vnition of the Opticks, is, that one eye being put out, the creature might see with the other; but it is more reasonable to say that Natures first intention was, that both the eyes should alwayes remaine sound.

The third reason is, that when one Eye is shut, all the visive spirits should hasten vnto the other to make the sight more acute or sharpe. But it may be answered that one Nerue cannot containe so much spirits as was in both. He that shootes at a marke in a Crosse-bow, or in a Peece, thinkes haply that he sees more sharply when he blinks of one eye then when he seeth his marke with both, but therein he is deceiued, for indeed he seeth not his marke so well, yet is able to lay his leuell better, because he seeth more directly when hee lookes through a narrow hole.

The fourth reason some conceiue to be, that when we are constrained to looke through a narrow hole, or by the same right line, by which both the eyes cannot discerne; in such a case the sight of both eyes might be vnited into one: But I doe not thinke (saith *Archangelus*) that Nature had any such scope in her first intention.

The fift and last reason giuen of the vnition, is the most probable, and that is, that these soft nerves might not be put to distresse in the middle of their passage, where (to say the truth) they are in most danger, as well because of their notable cavities, as also because of their softnesse, for they walke through the moister part of the braine, that is, the lower; and the faculty of seeing requires such a softnesse. Thus farre *Archangelus*.

The most probable of *Archangelus*.

They are called Opticke Nerves, that is, visive from their action, because they communicate the visive faculty or the sense of Seeing vnto the Eye. They are called also by *Herophilus* *meatus visorij*, because (saith he) they onely are sensibly bored, which also *Galen* approueth, who saith that they are manifestly perforated at each end. Many Dissectors are able to perceiue their perforation in the lower part where they touch the Eyes; but saith *Galen* in the fourth chapter of the 7 booke *De placitis*, he that would discerne the other perforation that is at their originall, must obserue three things. First, that the creature which he dissects be great: secondly, that the dissection bee made presently after death.

The names of the optickes.

Their perforations.

Whether the
Opticks be
perforated.
Opinions of
Anatomists.

death. Thirdly, that the ayre be cleare and lucide where he makes his dissection. He addeth also in the same place a reason why it was necessary that these nerves should rather be perforated then any other, and that is because these nerves do leade along the animall faculty by animall spirits or by a spirituall substance. For the rest they needed onely be porous without any hole or perforation, because the faculty in them is conuayed not by animall spirits but onely by a beaming irradiation. But the latter Anatomists with one consent do deny any such conspicuous perforation. *Vesalius*, I neuer met with it although I have cut vp dogs aliue and other large creatures only for this purpose, yea saith he I have opened the head of a man within lesse then a quarter of an houre after it was cut off, and haue carefully kept it warme with hot water, and yet could neuer find any such perforation. *Falopius* in his obseruations, The optickes are not manifestly perforated. *Columbus*, No pore or hole may be scene in them neither in an Oxe nor any greater creature. *Laurentius*, I neuer obserued any conspicuous cavity. *Volcher*, The opticke nerue is not made of a solid and perforated body, but of many nervous fibres bound and vnited by Membranes.

Questions
concerning
the spirits in
the nerves.

Thus you see that the streame of Anatomists runs directly against this opinion of *Galen*, and they render a reason, for say they, their substance being rare and soft, the spirit may easily passe through them vnto the eyes: yea all the sinewes although they haue no visible holes yet are they full of spirits, for the sense is hindred both by compression and by obstruction. So if a nerue be intercepted with a band or tye, the part below looseth sense, for the spirits of the vpper part being separated from the lower, there is no communion between them, but if the tye be taken away the sense returneth. And hence it is, that when the opticks are obstructed in that disease which the Arabians call *Gutta serena*, the action of seeing is vtterly taken away.

But whether wee are to belecue that in euery nerue there is a spirit as there is a spirit in the braine, which being perished the whole creature becommeth stupid, and being strong or plentiful serueth for the sense and motion of the parts; and whether if there be any such spirits they be inbred and seated in the nerue of the part, and onely awaked by a message from the braine, or whether at such time as we would moue any member, the motiue spirit falleth from the braine into the nerue, we confesse with *Galen* in the place before quoted, that we are not able absolutely to determine.

Bauhine des
termination.

Bauhine concludeth that these Nerves are not onely thicke and of a rare texture inuested by both the membranes of the braine, and fit to giue way for the transportation of the spirits, but also saith he, we belecue with *Galen* that they are porous as will especially appeare if they bee sodden, and *Archangelus* saith, that in the coition of the opticke nerves there is a common cavity insculped out of one into another. We say also with *Galen* in the eight chapter of his ninth booke *de vsu partium*, that the opticks in dignity are preferred worthily before the moouing Nerves of the eyes, because the principall part of vision or sight consisteth in them.

Moreouer saith *Bauhine* whilest they are yet in the Scull, certaine branches of the sleepe arteries do on either side touch them, which obseruation he tooke out of *Galen* in the place before quoted.

The vse of the
opticks.

The vse of the opticke nerves is one and the same according to all Anatomists, who herein do accord with *Galen*, that through them the sensatiue soule and the visive spirits are conuayed out of the marrow of the braine into the eyes.

The second
coniugation
of the eye-
mouers, their
originall.

The second coniugation of the braine is of the Nerves that mooue the eyes [Tab. 22, fig. 1 and 2, K] distinguished from the former coniugation onely by a thin bone. This coniugation is small and fine, much lesse then the former, and harder because it is to be inserted into muscles. It ariseth out of the basis of the marrow of the braine, and so runneth forward vnto the cavity of the eye, where it falleth out of the Scull through a proper hole accounted for the second perforation of the wedge bone.

Where they
passe the skull.

This hole is not round, as that which was bored for the optickes, but somewhat long, saith *Galen* in the eight chapter of his ninth booke *de vsu partium*, because three nerves were to passe through it: This, the third coniugation or the second branch of the third paire commonly so called; and the eight coniugation or the lesser roote of the fift paire, and therefore *Columbus* and *Archangelus* call it *Fissuram orbita*, a cleft or chinke of the Orbe of the eye.

The diuision
of this paire.

This moouing Nerue hauing perforated the bone, is fastned to the Opticke, and diuided into good large branches which are conuayed to the seuen muscles of the eye, saith *Vesalius* and *Platerus* to fve muscles of the eye, and to two of the eye-lid saith *Columbus* and *Archangelus*.

gelus; to foure onely of the eye; and that that lifteth vp the eye lid, saith *Falopius* and *Laurentius*.

Bauhine particularizeth concerning their insertion on this manner.

The first branch climbeth ouer the Opticke, and is disseminated into the muscle that lifteth vp the eye-lid, and the Muscle that lifteth vp the eye. The second, is very conspicuous vnder the Opticke and is diuided into many surcles and disperfed into the Muscle which leadeth the eye to the inner angle. The third is bifurcated and inserted in many strings into that Muscle which draweth the eye directly downward. The fourth is conuayed into the sixt Muscle which leadeth the eye round; or rowleth it vnto the vtter Angle.

There are also saith *Falopius*, and with him *Laurentius* and *Bauhine*, certaine small and threddy Fibres, which accompanying the Opticke Nerue are disseminated into the externall Membranes of the eye. In some men, through it be not very ordinary saith *Columbus* and *Archangelus* (but *Falopius* and *Laurentius* deny it) some branches are sent from this second Coniugation to the temporall muscle, whence it is that when that muscle is offended the eye partaketh with it, and on the contrary.

A consent be-
twixt the 2
coniugation
and the tem-
porall muscle.

The vse of this Coniugation is to conferre the Moouing faculty vnto the muscles and the tactiue faculty vnto the membrans of the eyes. Now the reason why when one eye is moued to one side, the other eye also followeth his motion necessarily, is to be ascribed to the Nerues themselues, which in their originall are continuall, that is, doe immediately ioyne together. And so much of the first and second Coniugations which are the Opticke and moouing Nerues of the eyes. Now we proceed.

The vse.

CHAP. XXIII.

Of the third and fourth Coniugations of the Braine.

THE third Coniugation [*tab. 22, fig. 1 and 2 L*] is sent vnto the muscles of the face and is commonly called the lesser roote of the third paire. But, saith *Bauhine*, because it is neuer ioyned with the Coniugation following [*ta. 22, fig. 1 and 2 L with M*] neither in the beginning nor in the progresse nor hath any thing common therewith, and because it groweth out of order in respect of all the rest, therefore saith he, it may worthily be called a peculiar Coniugation. It is saide to arise from that side of the basis of the Braine where the spinall marrow takes his originall. [*tab. 22, fig. 1 D*] But *Falopius* in his Obseruations hath it thus and better. It ariseth from the lower and backward part of the marrow of the Braine, or those processes thereof which are called the *Buttocks*. *Bauhine* addeth, that their originall is very small, and runneth directly vnder the basis of the braine to the side outward, and perforateth alone the *Dura meninx* on either hand. Then being fastned to the second paire [*tab. 22, fig. 1 K*] it entreteth into the orbe of the eye together with it by a perforation common to them both. And is diuided into foure branches according to *Vesalius*, *Columbus*, *Platerus* and *Bauhine*. But *Falopius* ascribeth these branches to the two subsequest coniugations which we haue reckoned but for one.

The 3 coniugation.

His originall.

Diuisiō.

The first of these [*tab. 22, fig. 2, N*] runneth vpward thorough the fat of the eyes and affoordeth a branch to the fist muscle placed in the inner angle (which compasseth it) vnto the pulley. *Falopius* is of opinion in his Obseruations that this whole Coniugation is bestowed vpon this muscle. But presently after the branch we made mention of before is bestowed, it falleth through a peculiar hole of the forehead bone to the skin of the forehead to giue it and the vpper eye-lid motion.

The second branch of this coniugation [*tab. 22, fig. 2 O*] is lower then the former and running downward passeth through a proper hole grauen for him in the fourth bone of the Iaw, at whose forepart it is diuided into many propagations distributed into the muscles that moue the vpper lippe and the Wing of the nose; outward into the lip it selfe, and the gums of those teeth that are called *Incisori* or the *shredders*.

The third branch [*table 22, fig. 2 P*] issuing through the second hole of the vpper iawe, behind the Caruncle seated in the angle of the eye, attaineth the eavity of the nosethrills where it is consumed into the coat, [*table 22, fig. 2 the lower P*] and affordeth a branch to the Membranous muscle of the nose which contracteth the wing thereof.

The fourth branch [*Table 22, figure 2 Q*] passing through the fissure which is betwixt the

bone

Table 22. Figure 1. sheweth the basis of the Braine, and After-braine, freed from their Membrane, that the originall of the Nerves of the Braine might be better perceived.

K K, 1, 2. the second paire of sinewes ordained for the motion of the eyes.

L L, 1, 2. the third paire of sinewes, or according to most Anatomists the lesser root of the third paire.

M M, 1, 2. the fourth paire of sinewes, or the greater root of the third paire.

N, 2. A branch of the third coniugation deriued to the musculous skin of the forehead.

O, 2. A branch of the same to the vpper iaw.

P P, 2. another into the coate of the nosethrills.

Q, 2. Another into the temporall muscle.

R, 2. A branch of the fourth coniugation crumpled like the tendrill of a Vine.

S, 2. A branch of the same reaching vnto the vpper teeth and the gummies.

T, 2. Another of the same to the lower iaw.

V, 2. a surcle of the branch T, to the lower lip.

XX, 2. other surcles from the branch T, to the roots of the lower teeth.

Y Y, 2. the assumption of the nerue of the fourth coniugation vnto the coate of the tongue.

Z, 1, 2. the fourth paire vulgarly so called which are spent into the coate of the pallat.

a, 1, 2. The fift paire of sinewes which belong vnto the hearing.

φ The Auditory Nerue spred abroad into the cavity of the stony-bone.

* A hard part of the fift coniugation about the * which may be accounted for a distinct Nerue.

b 1, 2. A small branch deriued from this harder part of the fift paire.

c 1, 2. A lower branch from the same originall.

d 1, 2. this Nerue is commonly ascribed to the fift paire, but indeed is a distinct coniugation which we will call the eight, because we would not corrupt the order of other mens accounts.

e 1, 2. The sixt paire of sinewes.

f 2, a branch from them deriued to the necke, and the muscles couched thereupon.

g 2. another branch to the muscles of the Larynx or thortle. h, 1, 2. the seuenth paire of sinewes.

i 1, the vnion of the seuenth paire with the sixt.

l 2, a propagation of the seuenth paire to those muscles which arise from the appendix called Styloides.

m 2. Surcles from the seuenth coniugation to the muscles of the tongue, the bone Hyois and the Larynx.

bone of the vpper iaw and the wedge-bone is consumed into the temporall muscle. And thus much of the third coniugation.

The fourth Coniugation.

The fourth coniugation belongeth to the tongue, and are called *Nervi gustatorij*, because by them the sense of gustation or tasting is made. [t. 22. fi. 2. M] This coniugation lieth close to the former in the progresse, but not in the originall, and is called by them that thinke it hath his beginning from a double root, it is called, I say, the thicker roote of the third coniugation. It doth not proceed, saith *Galen*, in the eighth chapter of his ninth booke *De vsu part.* out of the backe parts of the Braine, because those are hard, nor out of the sides, because the way had not been safe; but out of the basis of the Braine, where the fore-part is tyed to the hind-part, yea, out of the marrow of the Braine. And the reason of this originall is double: first, because it was most secure, and againe, because it was the readiest to answer the position of the tongue; from thence it falleth directly downward thorough the sixth hole of the wedge-bone, which is common to this and the following Coniugation, [Tab. 22. fig. 2. z.] and from this presently after the out-gate issueth a propagati-

on twisted or wrethed like the tendrils of a Veine, [tab. 22, fig. 2, R] that so, say some, it might by degrees become harder; or rather that the Animall spirit might haue a little stop or stay; and is vnited by two branches [Tab. 22, fig. 1, and 2, b c] with the auditory nerue. Sogiuing furcles to the muscles of the face, to the temporall muscles, to the grinding muscles of the cheekes and to the skinn of the face.

When it hath allowed this wrinkled branch, it descendeth more downward and fendeth forth a shoote [Tab. 22, fig. 2 s] which affoordeth furcles forward to the gums of the grinding teeth, and to the teeth themselues in their order, yet some doubt whether they passe as farre as the rootes of the teeth.

At the same time also there buddeth out of the backside a third propagation which *Falopius* calleth the fourth nerue of the third payre, [tab. 22, fig. 2, T] which is inserted into the muscle that lurketh in the mouth, and passing through the inner hole of the lower law offereth furcles to the roers of the lower teeth of his owne side, [tab. 22, fig. 2, x x] and by the helpe of these nerues the teeth (whereas other bones haue no sense) do feeble the occurrance of things that are offensiue. The remainder of this coniugation [ta. 22, fig. 2, V] neare the skinn, issu- ing through a hole bored in the foreside of the law is communicated to the lower lip and to the skin thereof in many furcles.

The remain-
der.

From this nerue also before it get into the law, there ariseth often a small sinew, slender indeed but strong and long which runneth vnder the law till it come to the muscle which openeth the mouth, and to those which are placed vnder the Chin, and is inserted partly in- to the bone Hyois and partly into the tongue.

Finally, the trunk of it selfe [tab. 21, fig. 2 T] which *Falopius* in his Observations calleth the fift nerue of the third coniugation, passeth through the muscles that lurke in the mouth, and being accompanied with the trunk of the other hand passeth vnto the side of the tongue and is consumed into the coate thereof to make it a fit organ to discern the differences of sapor or Tastes, and from it certaine small furcles are fixed into the substance of the tongue.

From this coniugation that which is commonly numbred for the fourth, by *Galen*, *Vesali- us*, *Columbus*, *Platerus*, and *Laurentius* [tab. 2, fig. 1, and 2, Z] seemeth not to be distinguished; not because it is nearest to that before named, but because it taketh his originall (though his furcles be many) out of one place, and in one place onely perforateth the *Dura meninx*. For those paires or coniugations which are commonly numbred for the sixt and the seauenth al- though they arise from many propagations, yet because the furcles are vnited together and so vnited do fall through one perforation of the *Dura meninx*, are not accounted for double or manifold paires, for we thinke with *Falopius* that in the distinguishing of the coniugations of the nerues the holes of the Scul are not to be considered; for if this were to be obserued, then because the second and the third paires and the eight do passe through one and the same hole they should be accounted all for one coniugation, which were yet neuer so accounted by any Anatomist.

How to count
the coniugati-
ons of the fi-
newes.

The originall of this nerue is lesser then the former, neare vnto it and a little harder, and therefore *Galen* saith, that it springeth more out of the Basis of the braine as from a part there- of which is the harder.

The originall
of it.

Presently after the originall, it passeth a little forward and is mingled with the third, with which it issueth at a common hole, and at the pallate is diuided into diuers branches, into whose whole coate it is inserted, [table 22, fig. 2 the lower Z] and giueth vnto it the sense of Tasting. *Galen* saith it is somewhat hard because the coate which compasseth the mouth is harder then the tongue and other parts of the mouth; and in this respect his sense is the duller. Sometime two small branches, which descend neare the Almonds and the Appendix called *Styloides* vnto the roote of the tongue are distributed through his coate. And thus much of the fourth coniugation.

CHAP. XXIII.

Of the Auditory Nerue or the fift Coniugation.

THE fift Coniugation [Tab. 22, fig. 1, and 2, a] at the sides of the basis of the braine according to *Galen*, ariseth out of the marrow of the braine elongated, and is made of two furcles or nerues. The one softer (and indeed the softest except the opticks) and nearest to the Eare, the other harder. These two do together issue through the membrane and run into the stony-bone, & many thinke

The fift co-
iugation.

thinke they are ioyned, accounting them for one nerue, for they say the fift Coniugation consisteth of a soft and a hard part, but indeed and truth they are distinguished. [ta. 22 fig. 2. It appeareth under a] which also *Galen* and *Falopius* did obserue.

His double
originall.

His out-gate.

Progress.

This Nerue therefore runneth through a large but writhen hole in the stony-bone, appointed properly for it, which is numbred for the fift perforation of the Temple-bone into the cavity which is like a Cony-burrough prepared for the organ of Hearing. Presently after, the harder part runneth forward through a proper Canale or Pipe, being accompanied with an artery arising from that artery which is disseminated through the *dura meninx*, and through the same bone it returneth obliquely backward, and falleth into that cavity wherein the *Timpanum* or Drum is, yet so that it alwayes butts vpon his owne bony Canale: from thence being more reflected it sendeth forth two shoots, one aboue and another below, both which do passe through by their proper holes. The vpper [ta. 22, fig. 1, and 2 b] runneth ouerthwart through the hole, through which likewise a small veine passeth vnto the Organ of Hearing. And this shoote is mixed [ta. 22, fig. 2 R] with that branch of the fourth paire, or of the third according to common Anatomists, which we said was like the tendrill of a vine: but the lower [tab. 22, fig. 2, c] passeth out at a hole which is very streight and writhen, and being carried ouerthwart over the *masseter* muscle, is instantly mixed with the branch of the third payre that is like the tendril of a vine, or to the propagation of the sinew that goeth vnto the tongue, and from the Tongue is led along to the muscles of the Cheekes, and to the skin about the roote of the outward eare; and haply this Nerue assisteth the Taft as well as the Hearing, and the reason may hence be deriued why those that are borne deafe are also borne dumbe. Sometime when this Nerue hath gottē through the blind hole it runneth downward as if it would accompany the sixt coniugation, [ta. 21, fig. 1 and 2, e] and sendeth small branches to the proper muscles of the *Larinx*, whence it is that because of the consent betwixt the Eares, the Tongue and the *Larinx*, a dry cough ariseth if we picke our Eares too deep. Sometime also it sendeth small branches into the whole arme, with the fourth, fift and sixt nerues of the arme, yea oftentimes it accompanieth the spinall marrow, and sendeth his branches together with the nerues of the marrow into the whole hand. But the soft part of this nerue [ta. 22, fig. 2 a] which is indeed *Nervus auditorius* the true Auditory Nerue, accompanieth the hard part, and when it hath attained vnto the end of the forenamed cavity it is dilated after the manner of a membrane and [ta. 22 fig. 1 and 2, d] becommeth the chiefe instrument of Hearing, and there remaineth after the same manner that we mentioned before in the expansion of the Organ of Smelling.

His branches

ditory nerue.

CHAP. XXV.

Of the sixt, seuenth and eight Coniugations.

The sixt con-
iugation.

THE sixt Coniugation [ta. 22, fig. 2 e] taketh his beginning from a few fibres a little below the originall of the fift payre or of the Auditory Nerue. But these fibres are presently and mutually vnited, and are thought to make one great nerue, whereas indeed they are not so vnited but that they remaine a good while two distinct nerues contained in one membrane which was the cause of the error. They get out of the Scull at the second hole of the Nowle-bone by which the greater branch of the internal *Iugular* veine did ascend into the braine. The one of these Nerues is the *anterior* and the lesse, the other is the *posterior* or the greater. The lesse when it hath gotten out of the Scull descendeth directly vnto the muscles of the Tongue (to whose roote it affoordeth a branch) and to those muscles which occupy the *Fauces* or chops, and into them most part of it is consumed.

His egress.

The greater Nerue not farre from his egress sendeth a branch backward, [tab. 22, fig. 2, f] which is distributed with many furcles into the muscles that occupy the necke, especially into the Cowle muscle which is the second of the shoulder-blade.

His descending
trunke.

The Trunke it selfe descending is connected or tyed to the seuenth Coniugation, [tab. 22, fig. 2, H] to the Sleepy artery and to the internal *Iugular* veine, by the interuening or interposition of a membrane, and at the sides of the *Larinx* or Throttle it is increased by a branch from the seuenth Coniugation [table 22, fig. 2, i] with which branch notwithstanding it is not mixed (for *Platerus* in this mixtion mist his marke) but colligated or tyed thereto. Presently after it sendeth furcles ouerthwart [tab. 22, fig. 2, g] vnto the muscles of the *Larinx*, especially those on the inside thereof. It affoordeth also a few small branches distinct from the former to the muscles of the *Fauces* or chops. From thence it descendeth

vnto

vnto the Chest and runneth quite through his capacity, as also thorough the capacity of the lower belly, and distributeth many branches vnto the bowels of both bellies, as we haue partly declared already and shall do hereafter towards the end of this booke. And because it runneth almost through all the bowels of the body, it is therefore called *Coniugatio vaga*, the gadding or wandering coniugation.

Falopius tells vs, that the Membrane wherewith this sixth nerue is inuested, as it falleth through the perforation assumeth vnto it selfe sometime manifestly, sometime secretly, a few small and capillary fibres of the nerue, and when it is out of the scull, produceth a certaine long body resembling an Oliue, which is sometimes single, sometimes double in both sides, and the colour fleshy, although the substance be neruous and hard.

Falopius his conceit of the Oliue-like bodies.

This *Oliue-like body* endeth into a certaine neruous fibre, which falling downe the necke, together with some propagations of nerues coupled together which issue from the first and second, and fourth and fift and sixt, or from the first and second, and fift and sixt and seuenth paires of the necke, doth make a texture or complication of vessells like a little net which descendeth on either hand downe the forepart of the whole necke; and in that complication, saith he, other new Oliue-like bodies do sometimes grow together, whose number is vncertaine, consisting of no other substance but as it were a heape of nerues growing together into a callous or fast body like a scarre. And this coniunction of nerues he calleth *sexti paris plexum*, the texture or complication of the sixth coniugation; from which texture many nerues, saith he, do descend vnto the basis of the heart. Herefrom also very often doth a nerue take his originall which on both sides is conueyed vnto the midriff, although it receiueth a further increment or encrease from the fourth and fift coniugations of the necke. He affirmeth further, that from this complication there issueth a nerue which descending through the chest along the roots of the ribs is conueyed to the roots of the Mesentery. Thus farre *Falopius*.

Now that from this sixth coniugation, nerues are sent vnto the bowells and not from the marrow contained in the rack-bones this reason may be giuen, because hauing not voluntary motion they did not stand in neede of so hard Nerues as do arise out of the spinall marrow properly so called; yet that they might not be altogether without Sense, they receiue Nerues of Sense, that is, soft nerues issuing out of the marrow of the Braine whilst it is yet contained in the scull, and the rather, saith *Galen* in the 11 chap. of his ninth Booke *de vsu partium*, because the substance it selfe of the bowels is but soft; but because these Nerues were to go a long journey, least they should be offended they are inuested with strong membranes, and besides fastned to the bodies by which they passe.

Why the bowelles haue nerues from this coniugation, and not from the spinall marrow?

It is also worth the obseruation that the nerues which are disseminated from the sixth coniugation into the trunke of the body, are as large almost at their terminations after they haue bene diuersly diuided and subdiuided as they are in the original, which cannot be said of any other vessell. It hath bene also publickly deliuered, I thinke from no other warrant but speculative Learning, that this nerue descendeth into the ioynts, and in the seete is the cause of the great consent betwixt the feet and the head. For mine owne part, I could neuer haue light of any such diuarcations out of Classicke Anatomists: beside, what neede we search for an imaginary way of consent, when we know that which is direct and agreed vpon by all, which is the branches of the nerues of the spinall marrow, wonderfully vnting themselves in the Tendons of the Muscles of the foote; by which any annoyance may at the first hand be conueyed vnto the marrow of the backe and so vnto the Braine.

A notable obseruation.

Moreouer, *Galen*s reason of the allowance of these Nerues of the sixth coniugation to the bowels in the place last before quoted were but of small moment if the feet also had nerues deriued therefrom. But this onely by the way.

A notuall conceire.

The seuenth coniugation, which *Archangelus* accounteth for the eighth, because he maketh the organs of smelling a coniugation of nerues: the seuenth coniugation I say [tab. 22. fig. 1 b, fig. 2 H] moueth the tongue and is the hardest of all those that yssue out of the Braine within the scull, and indeed it taketh his originall from a harder beginning, that is to say, in the hind-part of the Nowle-bone where the marrow of the Braine endeth saith *Galen* in the twelfth of his ninth Booke *de vsu partium*. From the beginning of the spinall marrow, saith *Vesalius*, but before it yssue out of the scull. From the Braine, not from the After-braine, saith *Columbus*. *Archangelus* saith from the backpart of the marrow where the cavity is that is compared to a writing pen. From the the marrow of the Braine, saith *Bauhine*, when it is ready to fall out of the scull [tab. 22. fig. 1 and 2 E] that is to say, at the very beginning of the spinall marrow properly so called. Thence therefore it ariseth with more roots then one, and those some-

The sixth coniugation.

His originall.

what

what distant one from another. But they vnite themselues and passe out of the scull by an oblique and proper perforation in the Nowle-bone, and for more security this Coniugation (saith *Galen* in the eleuenth of the ninth *de usu partium*) is ioyned by strong membranes with the sixt coniuigation, but not commixed therewith, saith *Falopius* in his Obseruations. For Retribution it communicateth to the sixt paire a portion of it selfe, [tab. 22. fig. 2 m] that is to say, sometimes one fibre or string and sometimes two, but the coniuigation it selfe keepeth still his owne body, and with a round and full thred runneth downward vnto the tongue, whose roote when it attaineth the greater part thereof [14. 22. fig. 22] is dissolued or as it were vntwisted and parted into many fibres, which as so many surcles are imparted into all the muscles of the tongue.

His implanta-
tion.

The lesser part sendeth some branches vnto the muscles of the bone *Hyois* and the Throttle to assist their motion. It affordeth also some surcles [tab. 22. fig. 2 l] vnto the muscles which take their originall from the appendix which is called *Styloides*. Finally, the fibres of the greater branch doe seeme to be commixed with the fibres of the fift coniuigation.

The eight
Coniugation.

The eight coniuigation (if we may so call them, which others do ascribe vnto the fift) [tab. 22. fig. 1 and 2 d] issueth out of the marrow of the Braine about the Auditory nerue, (and is much slenderer and harder then it) betwixt the second and third coniuigations. It runneth vpward & forward vnder the fibres of the basis of the Braine, and hauing perforated the *Dura meninx* betwixt the second and third coniuigations, it getteth into the orbe of the eye through the hole of the second coniuigation, saith *Banbinc*, according to *Falopius*, although *Vesalius* and *Platerus* thinke it passeth through a proper perforation in the wedge-bone, and so goeth vnto the temporall muscle and that which lurketh in the mouth; but the truth is, that it is almost wholly consumed in the muscle of the eye which draweth it to the viter angle.

Implantation.

This coniuigation, saith *Banbinc*, in regard of his originall should haue bene accounted before the fift and those that follow, but least in changing the number resolved vpon by Anatomists we should breed confusion, we haue rather thought good to reckon it in the last place. *Columbus* addeth a ninth paire, of which he challengeth the inuention, and for ought I know no man is desirous to take that prize out of his hand, which when they haue they shall not be able to hold; but he saith, that they be very small nerues arising from the two processes of the Braine, which are called *Nates* or the *Buttocks*, neere the Testicles; they bend their course toward the face, and passe out by the third and fourth coniuigations and are inserted into the third muscle of the eye-lid, but allow a branch also to the fift muscle of the eye. Thus farre *Columbus*.

Columbus his
ninth coniu-
igation.

And so much concerning the coniuigations of nerues seuen, or eight if you will, or nine if you beleue *Columbus*, which yssue from the marrow of the Braine contained yet within the Scull. Now we proceed vnto those that issue from the spinall marrow when it isalne out of the Scull.

CHAP. XXVI.

Of the Nerues which issue from the spinall Marrow in the Necke.

THE coniuigations before mentioned are called *productions* of the Brain, and *nerues* of the Braine, albeit they issue from the lengthened Marrow thereof, but yet contained within the Scull. Now we come vnto those sinewes which draw their originall from the same marrow indeed, but that contained in the rack-bones of the spine, and therefore are called *Nerues of the Spinall marrow*. For from this marrow all the parts which are vnder the face, excepting the bowels and the instruments of the voyce, do receiue Nerues; the bowels and the instruments of the voyce do not, partly because it was necessary that some of them should be immediately ioyned with the Braine, as the Heart and the Liuer, (for it behooued that all the principles of those faculties whereby the creature is gouerned should be conioyned) partly because their situation is neere vnto the Braine, and they stand in neede onely of Sense.

The Nerues of the spinall Marrow are accounted thirty Coniuigations yssuing out of distinct parts and seates, as out of the marrow of the Necke, the Chest, the Loynes, and the Holy bone contained within their *vertebra* or racke-bones, and out of their perforations

forations or the holes thrilled in them. These holes are either double, before and behind as in the two first of the necke and five of the Holy-bone, or single in each side of the racks, as in the rest.

The coniugations of the necke some account seven, as *Galen*, *Vesalius*, *Platerus*, and *Laurentius*, yet *Galen* in the first of the 13 *de usu partium* reckons 8, and so doth *Archangelus*; *Columbus* but five. These are dispersed into the outside of the whole head and his Muscles.

The first and second coniugation do not arise after the manner of other Nerues out of the sides of the spondels, one out of the right side, the other out of the left; but one falleth through the hole on the fore side, the other through the hole on the back side, which happeneth because of the different articulation of these two racks which is so made for the more security of the motion.

The first Coniugation issueth betweene the Nowle and the first racke-bone, which that it might more easily be, there is a certaine small cavity in the nowle-bone and in the first vertebra, (yet in dogs in whom the spondell is greater, the cavity is onely in it) but before it issue it is reflected about the spinall marrow and presently is diuided into two small branches, one anterior which is very small, [Tab. 23 H,] and so small that *Vesalius* saith it is not alwayes visible, but *Columbus* maketh no mention of it at all.

This nerue is inserted into the muscles which lye vpon the necke and vnder the gullet, which bend the necke, accounted by *Vesalius* and *Platerus* for the first payre that moue the backe, but *Bauhine* reckoneth it for the first bender of the necke, and calleth it *Longus* or the *Long-muscle*.

Table 23 is the same with Table 22. Lib. 7.

The other posterior [tab. 24, F] which is subdiuided into a double surcle, one lesser which is disseminated into the small muscles of the head seated in the *Occipitium* or nowle, the right branch into the muscles on the right side, and the left into the muscles of the left side, which also we must vnderstand of the nerues that follow. The other surcle of the posterior branch [tab. 24, e] goeth into the beginning of the muscle that draweth the shoulder blade vpward, for being but small they do not run beyond the muscles.

The second coniugation issueth with two beginnings, the fore branch [tab. 23, N] is very small and slippeth out betwixt the first and the second rack-bone at the sides of the tooth of the racke, and is distributed into the muscles that sit vpon the necke, as that branch of the first coniugation is of which wee spake ere while, with which branch it is implicated, and so consumed into the whole skin almost of the face.

The posterior branch which is the greater [table 24, I] when it is yssued by the side of the backward prolesse of the second racke-bone is presently diuided into two vnequall branches: the thicker [table 24, K] runneth ouerthwart toward the middle of the spine where the muscles do meete that occupy the necke, and is increased with a surcle [table 24, L] of the third coniugation, [table 23, S] and from the back-part tendeth vpward vnto the fore-part of the head, and disperfeth propagations into the skinned of the whole head euen to the top of the whole crowne, yea and vnto the eares, [tab. 23, and 24 MM] but the lesser branch [tab. 24, about B] is distributed into the beginnings of the third and sixt paires of muscles of the Head.

The third coniugation [table 23, char. 3,] breaketh out of a common hole which is betwixt the second and third spondell, and is diuided into two branches. The anterior whereof [tab. 23, P] is subdiuided into foure surcles, the first goeth to the first paire of muscles that bend the necke, the second [tab. 23, and 24, R groweth with T] runneth downward, and being commixed with a surcle of the fourth coniugation is distributed into the muscles that lye vnder the Gullet.

The third surcle [tab. 23, and tab. 24, from K to I] runneth vpward and meeteth with a branch of the second coniugation, and is spent into the skin on the sides and top of the head. The fourth [tab. 23, and 24, T] is disperfed into the muscles that incline the necke to the sides, as also vnto the muscle that lifteth vp the bladder. Finally, into that quadrangular muscle arising from the fleshy Membrane which draweth the lip obliquely downeward.

The posterior branch of the third coniugation [table 23, 24, O] is disseminated into the muscles that are common to the head and the necke, and lift it vp which are called *Sacer* and

7 of the necke.

and subdiuifi-
on.

and *semispinalis*. The first *Vesalius* accounteth for the seventh mouer of the backe, and the second for the eight.

The 4. coniugation.

The fourth Coniugation [*tab. 23 char. 4.*] issueth out of the common hole of the third and 4. Racke bones, and is diuided saith *Columbus* into many furcles. *Bauhine* saith into 2. branches, an *anterior* and a *posterior*: the *anterior* which is the greater is deuided into three propagations. [*tab. 23, and 24, X.*]

Diuisiō.

The first [*tab. 23, r.*] is mixed with a branch of the third paire [*tab. 23, R.*] and goeth to the muscles that lye vnder the Gullet, which make the first paire of Benders of the Necke.

The second [*tab. 23, a.*] departeth into the muscles that bend the necke into the sides, that is, into the second paire and to the second muscle of the shoulder-blade called *Cucullaris* or the Cowle muscle.

The third [*tab. 23, b.*] which is lesser, being accompanied with a branch of the fifth Coniugation [*tab. 23, c.*] and vnited with a propagation of the sixth [*tab. 23, m.*] descendeth neare the *Mediastinum* (where it letteth slip a small branch on each side) and aboue the *Pericardium*; that of these originalles, that is to say, the fourth mixed with the fifth and the sixth, the nerue of the Midriff [*tab. 23, and 24, n.*] might be compounded, which is inserted into his neruous tendon called by others his head. Sometime this branch of the fourth Coniugation is wanting, and then a furcle of the seventh Coniugation supplyeth the place, but howsoeuer, the chiefe part or mountenance of the Nerue is from the fifth Coniugation. The *posterior* branch of the fourth Coniugation which is also the lesse [*tab. 23, and 24, v.*] at the spine of the third Rack-bone bestoweth his blessing vpon the muscles of the necke, which lye vpon that spondell, and from thence is consumed into the membranous muscle of the cheekes.

The 5. coniugation.
His diuision.

The fifth Coniugation [*table 23, char. 3.*] falling out vnder the fourth spondell, is deuided into two branches, one *anterior* another *posterior*. The first furcle [*table 23, a d vnto char. 6.*] of the *anterior* branch [*table 23, and 24 d.*] goeth to the muscles which bend the necke. The second [*table 23, e.*] together with the propagations of the fourth and the sixth Coniugations [*table 23, out of bem.*] maketh the nerue of the Midriff. The third [*tab. 23 and 24, f.*] runneth vnto the muscle called *Deltoid*, which is the second of the arme from which small branches [*tab. 24 TT.*] are afforded to the muscles that lift vp the shoulder-blade called *Cucullaris* and *Leuator*.

From the same furcles also ariseth another Nerue [*table 23, and 24, g.*] which with many smal fibres is implicated in the skin that couereth the *Deltoid*; another lying deepe at the necke of the shoulder-blade is deuided into two branches, the *anterior* [*tab. 23, and 24, b.*] and the smaller affordeth small furcles to the *Deltoid*, where it taketh his original from the clauicle, sometimes also to the skin, accompanying the *humery* veyne.

Table 24. is the same with Tab. 23, Lib. 7.

The *posterior* which is the thicker [*tab. 23. 24, i.*] first sendeth a furcle into the second paire of muscles of the bone *Hyois* called *Coracohyoidei*: afterward being accompanied with a veine and an artery, it sendeth another to the vpper *super scapular* muscle or the vpper Blade-rider, againe vnto the *Deltoid* where it ariseth from the spine of the blade, and finally it sendeth furcles [*tab. 23. 24, n.*] to the outside of the skin of the arme. And so much of the *anterior* branch of the fifth Coniugation. The *posterior* [*tab. 24, e.*] at the tops of the spines is reflected and distributed like the *posterior* branch of the fourth Coniugation.

The sixth coniugation.
His diuision.

The sixth Coniugation which *Columbus* calleth the first paire of sinewes of the hand [*table 23, char. 6.*] vnder the fifth spondell where it issueth, is deuided into an *anterior* and *posterior* branch.

The *anterior* [*table 23, l.*] after it hath ioyned a propagation [*tab. 23, m.*] to the branch of the fifth Coniugation to make the nerue of the Midriff, is vnited with the seventh of the neck and the first Coniugation of the Chest. [*tab. 23, and 24, q.*] Afterward it is diuersly deuided, and with those that follow furnisheth out nerues to be transported to the Arme. It sendeth also a peculiar furcle [*tab. 24, p.*] vnto the hollow part of the shoulder-blade into the muscles that lift it vp.

The *posterior* branch [*tab. 24, k.*] is dispersed after the manner of the rest vnto the muscles which moue the head and the necke, as also into the heads of the muscles which serue for Respiration, which from the necke doe attaine vnto the Chest: those muscles also receiue nerues from the seventh Coniugation and from the first of the chest.

The

The seventh coniugation [*tab. 23. ch. 7.*] issueth vnder the sixt spondell of the necke, and for more security is ioyned with the sixt coniugation of the neck and the first of the chest, [*t. 33. f.*] the chiefe part whereof runneth into the arme, for the nerves of the arme are produced from the fift, sixt and seventh coniugations of the necke, and from the first and second of the chest.

The seventh
coniugation.
His division.

Sometime also there proceedeth from this coniugation a branch to the making of the nerue of the midriffe. Wherefore seeing that from the marrow of the necke many nerves do concur to the making of the midriffe-nerue, it is no wonder that in the Apoplexy the motion of the midriffe is for a while naturall, for although because of the obstruction of the ventricles of the braine, as it is commonly beleued, the animall spirit cannot be conveyed vnto the midriffe, yet seeing that the cavity of the spinall marrow containeth some deale of animall spirits, which by these nerves may be transported vnto the midriffe, and giue it a little motion, thence Respiration remaineth, and though it be but very little, yet the life is thereby sustained as long as the animall spirit shall remaine in the cavity of the spinall marrow, and if the obstruction of the ventricles can be freed, then he that is apoplectically, returneth to himselfe, if not, there he determines his life.

How a man
breathes in an
Apoplexy.

This is *Banbines* physiologie, concerning the apoplexy and the cause thereof, whereto though I can in no sort agree, yet because he handleth it but by the way, and we are now in another argument, I will not reason the case with him.

The posterior branch of the seventh coniugation [*tab. 24. t.*] which is also the lesse, and neuer missing, affordeth furcles to the muscles which lie vpon the necke, and vnto the square muscles of the cheekes; into which also furcles are sent from the fift coniugation of the braine, and from all seven of the necke, excepting onely the first, which furcles run according to the course of the fibres of the muscle: they attaine also vnto the skin. It is no wonder therefore, if the *Dog-spasme* be a grieuous disease, seeing that this muscle in it doth at the first hand suffer convulsion.

The dog-spasme.

Galen in the fift chap. of his 13 booke *de usu partium*, and after him *Archangelus* doe adde an eight coniugation, issuing betwixt the seventh and the eight spondels, and distributed especially into the cubit and the Ell, but passeth no further.

The 8 coniugation
after
Galen and
Vesalius.

CHAP. XXVII.

Of the Nerves of the Chest.

He nerves disseminated through the chest are double as well those that passe through the necke, for some take their originall from the braine, or rather from the marrow therof contained in the scull, others from his marrow passing through the racke-bones of the backe.

Of the nerves
of the Chest.

From the marrow of the braine proceedeth the sixt coniugation of the braine, which runneth through the chest, of which we haue partly spoken before, but will say more afterward in this booke.

From the spinall marrow contained in the back do issue eleuen coniugations saith *Vesalius*, but *Banbines* reckoneth twelue, all which after their egress are diuided into two branches, one greater and another lesse, one running forward and another reflected backward.

Twelue coniugations.

The first coniugation [*tab. 23. ch. 8.*] which *Vesalius* accounteth the eight of the spinall marrow, issueth betwixt the seventh rackebone of the necke, and the first of the chest on either side, and is diuided into two branches, one anterior, and another posterior.

The first coniugation.
His division.

The anterior, which is the greater, after it hath receiued an augmentation [*tab. 23, and 24. x.*] from the seventh coniugation, sometime also from the second of the Chest, and is diuersly commixed with the neighbour sinewes; attaining vnto the arme-pits, distributeth propagations [*tab. 24. aa.*] out of his backside into the hollow part of the blade, and so runneth away into the arme whose distribution we shall meet withall in that place.

Besides this, it sendeth also another branch [*tab. 23. y.*] vnto the arme, which running forward along the first rib, and so to the top of the brest-bone, bestoweth his blessing vpon the first muscle of the chest, called *subclanius*, and then is consumed or spent into the muscles which take their originall from the top of the brest-bone, as the muscle called *Mastoides*, *Sternohyoides*, and *Oesophagii*.

The posterior branch [*tab. 24. u.*] which is the lesser, is reflected vnder the muscles which grow vnder the Rack-bones, and in his transition affordeth small shoots to the second muscle of the necke, and those that moue the necke and the head backward; but when it hath

K k k k

attained

The 2 coniugation.

attained the spine of the seventh Rack-bone it departeth therefrom and offers surcles overthwart to the lower part of the cowle-muscle, the *Rhomboides* & the vpper & backward spine.

The second Coniugation [tab. 24, char. 9,] issueth betwixt the first and second racke of the Chest, and as the former it transmitteth and distributeth a branch backward [tab. 24, B,] afterward a good part is ioyned with a branch of the first coniugation [tab. 24, A] and runneth into the arme. The remainder proceedeth to the length of the first rib vnto the Chest and maketh the *Intercofall* nerue, from which certaine small surcles are distributed vnto the muscles that lye vpon the Chest.

The 3 and the nine following.

Their fore-branches.

The third and the other nine Coniugations [tab. 23 from char. 10, to char. 20,] of the chest are distributed after the same manner; for after they are issued out of the sides of the Racke-bones, they are deuided into two branches. The *anterior* branches which are called the *Intercofall* finewes [tab. 22, m] in their passage doe offer a surcle to the *Costall* nerue, which is said to be a branch of the sixth coniugation of the braine, and runneth vnder the *Pleura* vnto the rootes of the ribs: yea throughout his whole iourney they increase it with a small branch. For the branches themselves runne directly after the bent of the ribs through the distances betwixt them in a proper *sinus* or cavity insculped or grauen in the inner and lower side of euery rib for the transportation of these branches, together with a branch of the veine *Azygos* and the great artery which accompany them; and their course is forward vnto the *Pleura* neare the *Intercofall* muscles: so that the *Intercofall* veines of the true ribbes do reach as farre as to the brest-bone, those of the bastard ribbes do attaine vnto the fore side of the *abdomen* about the *Peritoneum*.

From these, diuers branches [tab. 23, 000 and the characters of the left side] are disseminated into the *Intercofall* muscles as wel internal as external, into the muscles that lie vpon the chest, [table 23, 00 11 xx] as the greater and lesser Saw, the *Pectorall* muscle and that which is called *Latissimus*, [tab. 23, uu] moreover into the oblique descendend muscle of the *Abdomen*, all which branches imitate the fibres of these muscles. They offer also small shootes sprinklingly vnto the skin of the chest.

These Nerves as also the rest, of course should haue beene inserted directly into the heads of the muscles, but nature hath reflected them backward into the veines, arteries and ligaments of that place. From the lower *Intercofall* nerves, some shootes also are communicated [tab. 22, aa] to the muscles of the *abdomen*.

Finally, from that *Intercofall* nerue which creepeth through the fourth distance of the ribs are certaine propagations [tab. 23, v] disseminated into the *Pectorall* muscles, from which there yssue some fine and small shootes vnto the paps giuing them a very exact sense. And so much for the *anterior* branches.

Their hinder-branches.

The *posterior* which are the lesser are reflected backward vnto the spines of the rackbones, and lurke amongst the muscles that grow vnto them, and are appointed to moue the Back and the Chest; yet are they not wholly consumed in these muscles, for when they haue touched the tops of the spines, they fall betweene the congresse or coniunction of the muscles of both sides, and are distributed into the muscles which arise from those heights of the Spines, as those that are called *Splenij*, *Romboides*, *Cucullaris*, *Latissimus*, *Serratus*, *Posticus inferior*, and some are distributed into the skin. But the distribution of Nerves into the skin is not one and the same in all bodies, and therefore can neither their order nor their number be certainly defined, for the trunks are deuided throughout the skin, sometime into more sometime into fewer branches.

To conclude, the two last coniugations of the chest doe offer surcles, *Columbus* saith to the fleshy part of the Midriffe. *Bauhine* [ta. 23, at the sides char. 18, 19] to the head of the muscle called *Lumbalis* or the sixth muscle of the Thigh.

CHAP. XXVIII.

Of the Nerves of the Loines.

The nerves of the loynes. 5 Coniugations.

He common and receiued opinion is, that from the spinall marrow contained in the rack-bones of the Loines doe arise five Coniugations of finewes which are greater then the coniugations of the chest, and issue out of the holes of the rackes of the Loines: herein agreeing with the nerves of the chest, that every coniugation is diuided into an *anterior* and a *posterior* branch, and that from the *posterior* branches [tab. 24, char. 52, 53] propagations are distributed into the muscles that grow vnto the rackes of the Loines. Among themselves they haue this also common saith *Galen*, that they are disseminated into the spinall muscles, the *Abdomen* and the flesh of the Loines.

The

The first coniugation [table 23, char. 20] as also the rest issuing at the holes of the spondyl under the Rim is divided into two branches, one *anterior* and greater, from which surcles are sent into the fleshy parts of the Midriffe, others vnto the head of the Muscle called *Lumbalis*, others vnto the muscles of the *Abdomen*. The *posterior* branch is the lesser and reflected into the muscles which lye vpon the racks of the Loines whereinto it is consumed as are the Surcles of the following coniugations. Such are the muscles called *Sacrilumbus*, *Longissimus* and *Sacer*. But where they issue from the tops of the spines they run into the sides and are disseminated into the skin of the arme and the broad Muscle called *Latissimus*.

The second coniugation [tab. 23, ch. 21] runneth vnder the sixt muscle of the thigh called *Lumbalis* vpon which it bestoweth small branches afterward: arising vp vnto the top of the haunchbone the *posterior* propagation thereof passing the *Abdomen* doth afford Sense and Motion to the first muscle of the thigh which make the buttockes, and to the first extender of the Legge called *Membranofus*. But the *anterior* branch is distributed into the seventh muscle of the thigh according to *Vesalius* and *Falopius*, but the sixt according to *Bauhine* and *Columbus* called *Iliacus internus*; into the first bender of the legge and vnto the skin of the thigh. From this coniugation also yssueth a small and long Nerue, [ta. 23, ch. 49] which together with the spermatieall vessels of his owne side is conuayed vnto the Testicles, which Testicles also receiue surcles from the *Costal* or rib-branch of the first coniugation of the Braine.

The third coniugation [tab. 23, ch. 22] issueth also vnder the *Lumbal* Muscle. His *anterior* branch passeth neere the haunch-bone and is divided into two propagations; One of which goeth vnto the knee and the skin thereof, the other accompanieth the veine called *Saphena*. But the *posterior* branch is reflected and disseminated into the Muscles that lye vpon the Loines and into the skin. In like manner from the *anterior* branches of the three first coniugations certaine surcles [ta. 23 at the sides, char. 20, 21, 22] apply themselves vnto the costall nerue and are ioyned therewith.

The fourth coniugation [ta. 23, ch. 23] which is the greatest of al the paires of the Loines, runneth vnder the *Lumbal*-muscle and the share-bone accompanying the veine and artery vnto the groine. *Columbus* obserueth, that it sendeth some propagations into the cod and the skin of the yard: but we, saith *Bauhine*, haue obserued that those partes do receiue small sinewes from the marrow of the holy-bone as *Galen* noted in his seuenteenth Booke *de dissectione Musculorum*, and after him *Archangelus*. It distributeth also other propagations, *Columbus* reckoneth seuen, vnto the *anterior* muscles of the thigh and legge, from which some surcles do descend as farre as to the knee.

The fift coniugation [tab. 23, ch. 24] like the rest is divided into two. The *anterior* and greater branch passeth through a hole betwixt the bone of the *Coxendix*, of the share and of the hanches, and distributeth propagations sometimes to both the muscles that compasse or bend the Thigh about; sometimes vnto the seventh and eight benders of the Thigh, sometimes vnto the muscles of the yard, though commonly they receiue nerves from the marrow of the Holy-bone. Item, branches vnto the necke of the bladder and of the wombe which also receiued nerves from the marrow of the Holy-bone. But the *posterior* branch is reflected and consumed into the muscles that sit vpon the racks of the Loines and into the skin of that place. Finally, from the three lower coniugations no small number of branches do reach vnto the Leg, as in that place we shall not forget to remember.

Moreover, these coniugations are hard and fastned one with another, the first with the second, the second with the third, the third with the fourth, the fourth with the fift, as it is demonstrated in the first figure of the 23 Table; after the same manner altogether as the nerves of the arme are implicated one within another.

CHAP. XXIX.

Of the nerves of the Holy-bone.

 Vt of the marrow concluded within the racks of the Holy-bone do issue fixe coniugations of Nerves. *Galen* reckoneth three of the Holy-bone, and three of the rumpe-bone. But *Vesalius* and *Columbus* doe heerein reprodue *Galen*, with what euidence of truth I cannot say, it appeareth manifestly that he was not ignorant of these bones euen in the bodies of men.

The first Coniugation [table 22, character 25] issueth betwixt the last racke-bone of the loynes

loynes and the first of the Holy-bone after the same manner as it was in the coniugations of the loynes, and is divided into an *anterior* and a *posterior* branch. The *Anterior* branch, although the greatest part thereof be mixed with the Nerves which are conveyed vnto the leg, yet notwithstanding it sendeth a propagation [ta. 23, ch. 53] vnto the inside of the haunch-bones from whence furcles are offered to the Muscles of the *Abdomen* and the seventh muscle of the thigh which is called *Iliacus internus*. The *posterior* branch runneth after the same manner as do the other Coniugations, and shooteth a propagation [ta. 24, ch. 54] into the muscles produced from the haunch-bone, especially into the first moouer of the Thigh from whence issue furcles consumed into the skin of the buttockes.

The five last.

Their anterior branches.

The five subsequent Coniugations [ta. 23, from ch. 26 to 30] are produced after one and the same manner: for before their egress they are on both sides double and on either side one Nerve falleth forward, and on either side one Nerve backward. The three vpper Anterior or forward nerves, as also that of the first coniugation, doe run vnto the leg: the two lower vnto the muscles of the fundament and the bladder, haply also to the priuy parts, in some bodies vnto the Necke of the Wombe, of the bladder, and of the yard. Finally, others are conveyed vnto the *Perinæum*, that is, the place betwixt the Cods and the Fundament, and vnto the cods themselves.

Their posterior branches.

The Posterior branches [ta. 24, ch. 54 55] are distributed into the muscles which take vp the *posterior* part of the haunch and holy bones; into the muscle of the backe called *Longissimus*; into that which is called *Sacer* or the holy Muscle; into the Membranous beginning of the broad muscle of the Arme and the fixt of the Chest called *Sacrolumbus*: finally into the fore extenders of the thigh, and into the skin of the buttockes.

But the termination or end of the spinall Marrow [ta. 23 and 24, ch. 56] issuing out of the Holy-bone both on either side part with a propagation which sometimes is distributed into many furcles on the right hand and on the left, which is disseminated through the fourth muscle of the thigh through the skin which is betwixt the buttockes even vnto the fundament; yet some say that it is distributed as other nerves are, and call it *Nervum sine coniuge* the Nerve without a companion: and thus it is in man. But in Apes and Dogs there are three Coniugations of which the two lower onely are produced forward and backward; the rest of the Coniugations issue out at the sides of the rumpe bone, as they do out of the rack-bones of the Chest and of the Loynes.

The summe of all.

How necessary the knowledge of this is for Chirurgions.

From this History of the Nerves of the spinall marrow we conclude that it hath thirty coniugations or paires of Nerves, seven of the marrow of the necke, twelve of the marrow of the backe or of the Chest, five of the marrow of the Loynes, six of the marrow of the Holy-bone. And all these with their severall originals, places of egress and distributions, not onely Physicians but Surgeons also ought necessarily to know that they may be able to apply their Vnguents and Cataplasmes vnto the right places of the spine or ridge when either the Nowle, or the face, or the necke, or the hands, or the partes of the chest, or the muscles of the *Abdomen*, or the wombe, or bladder, or the fundament, or the yard, or the legs shall bee deprived of motion or sense, or both together. Thus much concerning the nerves of the spinall marrow, and the parts thereof.

CHAP. XXX.

Of the Nerves of the Hand in the large acception,

The Hand,

H B Hand is the Instrument of Instruments, that is to say, the Instrument of the minde or Soule whereby she frameth and fashioneth all Instruments which consist of any matter whatsoever, or haue respect vnto any commodity or profit of man. And therefore that it might more freely do the service it was ordained for, it hath in allowance not only muscles the instruments of voluntary motion, and veines which convey bloud and nourishment vnto it, and arteries to give it vigour and vivacity: but also it hath nerves as well to convey the motiue vertue vnto the muscles, as also to furnish it with the most exact sense of touching. There are therefore disposed vnto the Hand sometimes five paires of sinewes, sometimes sixe, arising from the spinall Marrow contained in the rack-bones of the Necke and Chest, that is to say, out of the fift, sixt and seventh of the Necke, and the first and second rackes of the chest. These Nerves do issue out of the common perforations of the aforesaid rack-bones, and presently after their egress are united at the sides of the spondels: after-

Hath 5 paires of sinewes.

afterward they are separated, againe conioyned, and finally separated, so seeming to make the mesh of a net, [ta. 25, fi. 3.] For, saith *Columbus* and that out of *Vesalius*, it is like the strings of a Cardinals hatte. This implication was made for more security that the nerves which were to walke a longer iourney might become harder, and so stronger to propulse or endure any iniury that might be offered vnto them.

These nerves run vnder the clauike or cannel bone vnto the inner processe of the shoulder-blade, where the Basilica veine and the Axillary artery keepe their way, and hence it is that wounds in this place are so very dangerous, and luxations of the shoulder do easily bring a consumption vpon the Patient.

Why wounds about the clauike are dangerous, and the luxation of the shoulder.

From this fore-said implication or complication of the sinewes do the nerves of the hand or of the arme arise, and creepe betwixt the skin and the fleshy membrane deeply drenched in fatte in the bodies of men, and by their mediation that fleshy membrane is indissolubly fastned to the skin, but they do not alwayes retaine the same magnitude position and number; alwayes they are distributed into many backward branches, but the greater nerves Nature hath worthily distributed into the insides of the hand because by them it performeth all his actions.

The first nerve of the hand is a surcle of a branch of the fist nerve of the necke [tab. 25, fig. 1,] which runneth through the vpper and externall part of the arme, [table 25, fig. 1 and 2, f] and is diuided into two branches. The one vpper, which is sent vnto the muscle called *Deltoides*, [table 25, fig. 1, and 2, b] from which a branch [table 25, fig. 1, and 2, g] is communicated to the skin that lyeth vpon the same muscle being accompanied with the humerary vein. The other being accompanied with a vein and an artery, at the sinus or bosome of the blade passeth on vnto the second muscle of the bone *Hyois* called *Coracohyoideus* which occupieth the vpper part of the shoulder-blade, and to a part of the *Deltoides* and the skinn of the middle of the arme on the vpper side, [table 25, figure 1, and 2, i] and maketh the first nerve of the arme. [ta. 25, fig. 1, 100] It determineth a little vnder the middest of the length of the arme.

The first nerve of the hand.

The second nerve of the hand [table 25, fig. 1, e] is bigger, and taketh his beginning from the complication which the nerves that are to goe vnto the arme do make at the sides of the rackbones. Thence it falleth by the anterior and middle part of the Cubit, and first of all communicateth a small branch to the muscle called *Biceps* which is the first of the Cubit, [ta. 25, figure 1, 100] afterward it ioyneth with the third nerve, [Table 25, figure 1, and 2, r] and after the coniunction it creepeth downward, [table 25, figure 1, o] and from the outside sendeth a small branch [table 25, figure 1, r] to the muscle of the Wand called *Supinator longior*. But when it hath attained vnto the bent of the cubit it is diuided into three branches, (sometimes into two, but then the lower is againe subdivided) one vpper and smaller, [table 25, figure 1, creeping from the vpper E vnto the lower E] which passing a good way by the outside of the arme with a branch of the humerall veine runneth vnto the outside sometime of the first, sometime of the second ioynt of the thumb, and intertexeth that part with small surcles. The second [table 25, figure 1, o] is the middle-most and something larger then the former. It lyeth vnder the foresaide humerall veine where the Median or Common veine ariseth thereout (and descendeth with an oblique passage along the cubit, but aboue the fleshy pannicle) euen vnto the wrest. [table 25, fig. 1, 100 above 44.] The third is the lowest. [table 25, fig. 1, 100] His progresse is somewhat oblique and is fastened to the interior branch of the Basilica veine, and in the cubit is diuided into two branches, [tab. 25, fig. 1, 100] at length ouercomming the wrest it distributeth surcles to the skin on the inside of the hand, from which sometimes small shootes do attaine vnto the outside of the thumbe, which are commixed with the surcles of the posterior branch.

The second.

His diuision into three branches.

The third nerve of the hand [table 25, fig. 2, r] runneth through the fore and lower side of the cubit and vnder the double-headed muscle in the arme is increased with a branch of the second nerve. [tab. 25, fig. 1, 100] Presently after it is diuided and affoordeth two branches to the skin on the forepart of the arme [tab. 25, fig. 1 v betwixt 1 and 2.] When it hath attained vnto the bent of the cubit, it is mingled with the fist paire, [table 25, fig. 1 ch. 43] and sendeth small branches vnto the muscles which grow out of the inner protubetation of the arme: from hence it reacheth a notable branch obliquely to the *Radius* or wand, [ta. 25, fi. 1 ch. 44] which being accompanied with a veine and an artery is parted into 3, and runneth into the inside of the hand, communicating 2 surcles to the thumbe, two to the fore finger, and one to the vpper side of the middle finger. And when this middle finger doth not receiue a surcle from the fist nerve, then it alloweth two to the middle & sometimes one to the Ring-finger.

The third.

Table 25. Fig. 1. and 2. sheweth the Nerves of the whole hand, the first figure sheweth their fore-side, the second their back-side.

TABVLA XXV.

7 1, a branch of the eight paire going to the top of the breast. 2 2, Surcles from the eight paire going vnto the muscles of this place. charact. 9. in the first figure, the ninth paire of nerves. 8 1, the hinder branch of the ninth paire. 9 2, the fore branch of this coniugation. 10 1, the first nerve of the arme going vnto the skinn. 1 1, the second nerve of the arme. 11 1, From this doe proceed nerves going vnto the first muscle of the Cubit called *Biceps*. 12 1, the third nerve of the arme. 13 1, a branch thereof to the skinn of the arme. 14 1, A small branch going vnto second muscle of the cubit, called *Brachialis*. 15 1, to the skinn of the fore-side of the arme. 16 1, the meeting of the third nerve with the second. 17 1, the second nerve, together with the third, creeping downward. 18 1, a nerve to the second muscle of the *Radius*, called *Supinator longior*. 19 1, the diuision of the second nerve into three branches. 20 1, the vpper or first branch of the second nerve, running vnto the wrist, and so vnto the first ioynt of the thumbe. 21 1, the middle branch of the second nerve. 22 1, his progresse euen vnto the hand. 23 1, the lower and third branch of the second nerve. 24 1, two branches of this nerve going vnto the inside of the hand. 25 1, 2, the fourth nerve of the arme. 26 2, nerves from this vnto the extending muscles of the Cubit. 27 1, a branch vnto the skinn on the back-side of the arme. 28 2, to the skinn on the outside of the arme. 29 2, A branch creeping along the outside of the Cubit vnto the wrist. 30 2, the bypartition of the fourth nerve at the Cubit. 31 2, the vpper branch of the said diuision. 32 2, the surcles which belong to the thumbe, the forefinger and the middle finger on their out-side. 33 2, the lower branch of the afore-said diuision. 34 2, surcles therefrom vnto the muscles arising from the externall prouuberation of the arme. 35 2, 36, 37, 38, 39, 40, 41, 2, three branches going to the muscles that arise from the *Vlna* or *El.* 42 2, the end of the branch 37, neare the ioynt of the wrist. 43 1, 2, the fifth nerve of the arme. 44 1, Propagations of the third and fifth nerves, vnto the inside of the Cubit. 45 1, a branch of the third nerve, going vnto the palme of the hand and the fingers. 46 1, a branch of the fifth nerve vnto the inside of the hand. 47 1, a propagation of the branch 45, vnto the outside of the hand. 48 1, 2, the sixth nerve of the arme. 49 1, his end neare vnto the ioynt of the hand. 50 1, 2, surcles from the sixth nerve vnto the skinn.

Figure 3. Sheweth the complication of the Nerves which come vnto the arme out of Vesalius.

Char. 5, 6, 7, 8, 9. The rootes of those coniugations from which nerves are produced vnto the arme. A A, portion out of the fifth paire of the first nerve. B, the second nerve. C, the third nerve. D D, the fourth nerve which issueth out of the back-side of the congreffe or coniunction of the fifth paire and the sixth, it assumeth a portion out of the back-side of the coniunction of the seventh paire, and after creeping vnder the coniunction of the eighth and ninth paires, it also assumeth a portion therefrom. E, Which is the branch marked with E. F, the fifth nerve that runneth into the arme. G, the sixth nerve deriued into the arme.

A, the spinall marrow getting into the Racke-bones.

charact. 1, 2, 3, 4, 5, 6, 7, 8, 9. Seauen rackbones of the necke, and two of the Chest;

c 2, the forward branch of the fift paire.

f 1, 2, a branch of the nerve d, creeping to the top of the shoulder, vnder which are surcles going to the shoulder-blade.

g 1, 2, Propagations of the nerve f, going to the skin of the top of the shoulder.

h 1, 2, a branch of the nerve f, going vnto the second muscle of the arme.

i 1, 2, another branch inserted into the same and to the skin.

charact. 6, in 1, the sixt coniugation of sinewes.

k 2, the hinder branch of the sixth paire.

l 1, the fore branch of the sixth paire.

m 1, 2, a surcle thereof that maketh the nerve of the midriffe.

p 2, a branch of the sixth paire, reaching vnto the cavity of the shoulder-blade.

q 1, 2, the complication of the branch l, with the neighbour branches.

charact. 7, in the first fig. The seuenth paire of nerves.

r 2, the hinder branch of the seuenth paire.

s 1, the congreffe or meeting of the seuenth paire, with his neighbour branches.

t 1, 2, some surcles hereof going vnto the muscles of the shoulder-blade and the arme.

u 2, the hinder branch of the eighth paire.

v 1, 2, the congreffe or meeting of the eighth paire with the seuenth.

The fourth into the Arme, along the back-side, and passing along the back-side of the cubit [Tab. 29, fig. 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100, 101, 102, 103, 104, 105, 106, 107, 108, 109, 110, 111, 112, 113, 114, 115, 116, 117, 118, 119, 120, 121, 122, 123, 124, 125, 126, 127, 128, 129, 130, 131, 132, 133, 134, 135, 136, 137, 138, 139, 140, 141, 142, 143, 144, 145, 146, 147, 148, 149, 150, 151, 152, 153, 154, 155, 156, 157, 158, 159, 160, 161, 162, 163, 164, 165, 166, 167, 168, 169, 170, 171, 172, 173, 174, 175, 176, 177, 178, 179, 180, 181, 182, 183, 184, 185, 186, 187, 188, 189, 190, 191, 192, 193, 194, 195, 196, 197, 198, 199, 200, 201, 202, 203, 204, 205, 206, 207, 208, 209, 210, 211, 212, 213, 214, 215, 216, 217, 218, 219, 220, 221, 222, 223, 224, 225, 226, 227, 228, 229, 230, 231, 232, 233, 234, 235, 236, 237, 238, 239, 240, 241, 242, 243, 244, 245, 246, 247, 248, 249, 250, 251, 252, 253, 254, 255, 256, 257, 258, 259, 260, 261, 262, 263, 264, 265, 266, 267, 268, 269, 270, 271, 272, 273, 274, 275, 276, 277, 278, 279, 280, 281, 282, 283, 284, 285, 286, 287, 288, 289, 290, 291, 292, 293, 294, 295, 296, 297, 298, 299, 300, 301, 302, 303, 304, 305, 306, 307, 308, 309, 310, 311, 312, 313, 314, 315, 316, 317, 318, 319, 320, 321, 322, 323, 324, 325, 326, 327, 328, 329, 330, 331, 332, 333, 334, 335, 336, 337, 338, 339, 340, 341, 342, 343, 344, 345, 346, 347, 348, 349, 350, 351, 352, 353, 354, 355, 356, 357, 358, 359, 360, 361, 362, 363, 364, 365, 366, 367, 368, 369, 370, 371, 372, 373, 374, 375, 376, 377, 378, 379, 380, 381, 382, 383, 384, 385, 386, 387, 388, 389, 390, 391, 392, 393, 394, 395, 396, 397, 398, 399, 400, 401, 402, 403, 404, 405, 406, 407, 408, 409, 410, 411, 412, 413, 414, 415, 416, 417, 418, 419, 420, 421, 422, 423, 424, 425, 426, 427, 428, 429, 430, 431, 432, 433, 434, 435, 436, 437, 438, 439, 440, 441, 442, 443, 444, 445, 446, 447, 448, 449, 450, 451, 452, 453, 454, 455, 456, 457, 458, 459, 460, 461, 462, 463, 464, 465, 466, 467, 468, 469, 470, 471, 472, 473, 474, 475, 476, 477, 478, 479, 480, 481, 482, 483, 484, 485, 486, 487, 488, 489, 490, 491, 492, 493, 494, 495, 496, 497, 498, 499, 500, 501, 502, 503, 504, 505, 506, 507, 508, 509, 510, 511, 512, 513, 514, 515, 516, 517, 518, 519, 520, 521, 522, 523, 524, 525, 526, 527, 528, 529, 530, 531, 532, 533, 534, 535, 536, 537, 538, 539, 540, 541, 542, 543, 544, 545, 546, 547, 548, 549, 550, 551, 552, 553, 554, 555, 556, 557, 558, 559, 560, 561, 562, 563, 564, 565, 566, 567, 568, 569, 570, 571, 572, 573, 574, 575, 576, 577, 578, 579, 580, 581, 582, 583, 584, 585, 586, 587, 588, 589, 590, 591, 592, 593, 594, 595, 596, 597, 598, 599, 600, 601, 602, 603, 604, 605, 606, 607, 608, 609, 610, 611, 612, 613, 614, 615, 616, 617, 618, 619, 620, 621, 622, 623, 624, 625, 626, 627, 628, 629, 630, 631, 632, 633, 634, 635, 636, 637, 638, 639, 640, 641, 642, 643, 644, 645, 646, 647, 648, 649, 650, 651, 652, 653, 654, 655, 656, 657, 658, 659, 660, 661, 662, 663, 664, 665, 666, 667, 668, 669, 670, 671, 672, 673, 674, 675, 676, 677, 678, 679, 680, 681, 682, 683, 684, 685, 686, 687, 688, 689, 690, 691, 692, 693, 694, 695, 696, 697, 698, 699, 700, 701, 702, 703, 704, 705, 706, 707, 708, 709, 710, 711, 712, 713, 714, 715, 716, 717, 718, 719, 720, 721, 722, 723, 724, 725, 726, 727, 728, 729, 730, 731, 732, 733, 734, 735, 736, 737, 738, 739, 740, 741, 742, 743, 744, 745, 746, 747, 748, 749, 750, 751, 752, 753, 754, 755, 756, 757, 758, 759, 760, 761, 762, 763, 764, 765, 766, 767, 768, 769, 770, 771, 772, 773, 774, 775, 776, 777, 778, 779, 780, 781, 782, 783, 784, 785, 786, 787, 788, 789, 790, 791, 792, 793, 794, 795, 796, 797, 798, 799, 800, 801, 802, 803, 804, 805, 806, 807, 808, 809, 810, 811, 812, 813, 814, 815, 816, 817, 818, 819, 820, 821, 822, 823, 824, 825, 826, 827, 828, 829, 830, 831, 832, 833, 834, 835, 836, 837, 838, 839, 840, 841, 842, 843, 844, 845, 846, 847, 848, 849, 850, 851, 852, 853, 854, 855, 856, 857, 858, 859, 860, 861, 862, 863, 864, 865, 866, 867, 868, 869, 870, 871, 872, 873, 874, 875, 876, 877, 878, 879, 880, 881, 882, 883, 884, 885, 886, 887, 888, 889, 890, 891, 892, 893, 894, 895, 896, 897, 898, 899, 900, 901, 902, 903, 904, 905, 906, 907, 908, 909, 910, 911, 912, 913, 914, 915, 916, 917, 918, 919, 920, 921, 922, 923, 924, 925, 926, 927, 928, 929, 930, 931, 932, 933, 934, 935, 936, 937, 938, 939, 940, 941, 942, 943, 944, 945, 946, 947, 948, 949, 950, 951, 952, 953, 954, 955, 956, 957, 958, 959, 960, 961, 962, 963, 964, 965, 966, 967, 968, 969, 970, 971, 972, 973, 974, 975, 976, 977, 978, 979, 980, 981, 982, 983, 984, 985, 986, 987, 988, 989, 990, 991, 992, 993, 994, 995, 996, 997, 998, 999, 1000.

The secon the wand vnto two furcles finger.

The third muscles that of the wrist with the

The fifth complication bend the cub lower side of the arme [Tab. 25, fig. 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100, 101, 102, 103, 104, 105, 106, 107, 108, 109, 110, 111, 112, 113, 114, 115, 116, 117, 118, 119, 120, 121, 122, 123, 124, 125, 126, 127, 128, 129, 130, 131, 132, 133, 134, 135, 136, 137, 138, 139, 140, 141, 142, 143, 144, 145, 146, 147, 148, 149, 150, 151, 152, 153, 154, 155, 156, 157, 158, 159, 160, 161, 162, 163, 164, 165, 166, 167, 168, 169, 170, 171, 172, 173, 174, 175, 176, 177, 178, 179, 180, 181, 182, 183, 184, 185, 186, 187, 188, 189, 190, 191, 192, 193, 194, 195, 196, 197, 198, 199, 200, 201, 202, 203, 204, 205, 206, 207, 208, 209, 210, 211, 212, 213, 214, 215, 216, 217, 218, 219, 220, 221, 222, 223, 224, 225, 226, 227, 228, 229, 230, 231, 232, 233, 234, 235, 236, 237, 238, 239, 240, 241, 242, 243, 244, 245, 246, 247, 248, 249, 250, 251, 252, 253, 254, 255, 256, 257, 258, 259, 260, 261, 262, 263, 264, 265, 266, 267, 268, 269, 270, 271, 272, 273, 274, 275, 276, 277, 278, 279, 280, 281, 282, 283, 284, 285, 286, 287, 288, 289, 290, 291, 292, 293, 294, 295, 296, 297, 298, 299, 300, 301, 302, 303, 304, 305, 306, 307, 308, 309, 310, 311, 312, 313, 314, 315, 316, 317, 318, 319, 320, 321, 322, 323, 324, 325, 326, 327, 328, 329, 330, 331, 332, 333, 334, 335, 336, 337, 338, 339, 340, 341, 342, 343, 344, 345, 346, 347, 348, 349, 350, 351, 352, 353, 354, 355, 356, 357, 358, 359, 360, 361, 362, 363, 364, 365, 366, 367, 368, 369, 370, 371, 372, 373, 374, 375, 376, 377, 378, 379, 380, 381, 382, 383, 384, 385, 386, 387, 388, 389, 390, 391, 392, 393, 394, 395, 396, 397, 398, 399, 400, 401, 402, 403, 404, 405, 406, 407, 408, 409, 410, 411, 412, 413, 414, 415, 416, 417, 418, 419, 420, 421, 422, 423, 424, 425, 426, 427, 428, 429, 430, 431, 432, 433, 434, 435, 436, 437, 438, 439, 440, 441, 442, 443, 444, 445, 446, 447, 448, 449, 450, 451, 452, 453, 454, 455, 456, 457, 458, 459, 460, 461, 462, 463, 464, 465, 466, 467, 468, 469, 470, 471, 472, 473, 474, 475, 476, 477, 478, 479, 480, 481, 482, 483, 484, 485, 486, 487, 488, 489, 490, 491, 492, 493, 494, 495, 496, 497, 498, 499, 500, 501, 502, 503, 504, 505, 506, 507, 508, 509, 510, 511, 512, 513, 514, 515, 516, 517, 518, 519, 520, 521, 522, 523, 524, 525, 526, 527, 528, 529, 530, 531, 532, 533, 534, 535, 536, 537, 538, 539, 540, 541, 542, 543, 544, 545, 546, 547, 548, 549, 550, 551, 552, 553, 554, 555, 556, 557, 558, 559, 560, 561, 562, 563, 564, 565, 566, 567, 568, 569, 570, 571, 572, 573, 574, 575, 576, 577, 578, 579, 580, 581, 582, 583, 584, 585, 586, 587, 588, 589, 590, 591, 592, 593, 594, 595, 596, 597, 598, 599, 600, 601, 602, 603, 604, 605, 606, 607, 608, 609, 610, 611, 612, 613, 614, 615, 616, 617, 618, 619, 620, 621, 622, 623, 624, 625, 626, 627, 628, 629, 630, 631, 632, 633, 634, 635, 636, 637, 638, 639, 640, 641, 642, 643, 644, 645, 646, 647, 648, 649, 650, 651, 652, 653, 654, 655, 656, 657, 658, 659, 660, 661, 662, 663, 664, 665, 666, 667, 668, 669, 670, 671, 672, 673, 674, 675, 676, 677, 678, 679, 680, 681, 682, 683, 684, 685, 686, 687, 688, 689, 690, 691, 692, 693, 694, 695, 696, 697, 698, 699, 700, 701, 702, 703, 704, 705, 706, 707, 708, 709, 710, 711, 712, 713, 714, 715, 716, 717, 718, 719, 720, 721, 722, 723, 724, 725, 726, 727, 728, 729, 730, 731, 732, 733, 734, 735, 736, 737, 738, 739, 740, 741, 742, 743, 744, 745, 746, 747, 748, 749, 750, 751, 752, 753, 754, 755, 756, 757, 758, 759, 760, 761, 762, 763, 764, 765, 766, 767, 768, 769, 770, 771, 772, 773, 774, 775, 776, 777, 778, 779, 780, 781, 782, 783, 784, 785, 786, 787, 788, 789, 790, 791, 792, 793, 794, 795, 796, 797, 798, 799, 800, 801, 802, 803, 804, 805, 806, 807, 808, 809, 810, 811, 812, 813, 814, 815, 816, 817, 818, 819, 820, 821, 822, 823, 824, 825, 826, 827, 828, 829, 830, 831, 832, 833, 834, 835, 836, 837, 838, 839, 840, 841, 842, 843, 844, 845, 846, 847, 848, 849, 850, 851, 852, 853, 854, 855, 856, 857, 858, 859, 860, 861, 862, 863, 864, 865, 866, 867, 868, 869, 870, 871, 872, 873, 874, 875, 876, 877, 878, 879, 880, 881, 882, 883, 884, 885, 886, 887, 888, 889, 890, 891, 892, 893, 894, 895, 896, 897, 898, 899, 900, 901, 902, 903, 904, 905, 906, 907, 908, 909, 910, 911, 912, 913, 914, 915, 916, 917, 918, 919, 920, 921, 922, 923, 924, 925, 926, 927, 928, 929, 930, 931, 932, 933, 934, 935, 936, 937, 938, 939, 940, 941, 942, 943, 944, 945, 946, 947, 948, 949, 950, 951, 952, 953, 954, 955,

The fourth Nerve [*tab. 25, fig. 1, and 2, **] which is the largest of all the Nerves that runne into the Arme, taketh his beginning from the complication we spake of before. It runneth along the backward and vpper part of the cubit ouer the external protuberation of the arme, and passing along with the *Deepe-veine* and the Axillary artery, it inflecteth it selfe at the vter and back-part of the arme, and distributeth two branches to the extending muscles of the cubit [*tab. 29, fig. 2, **] and to the skin which is at the ioynt, and vnto the backpage, and another vnto the vter part. [*tab. 25, fig. 2, and char. 32, **] Afterward neare the ioynt of the cubit at the externall protuberation of the arme [*tab. 25, fig. 2, char. 34, **] it is sometimes deuided into two trunks which lye deepe as doth their roote; [*char. 35, 37, **] sometimes it is diuided into three branches, [*char. 33, 35, 37, **] whereof the exterior [*tab. 25, fig. 2, char. 33, **] runneth along the outside of the cubit wherevpon it bestoweth branches and descendeth obliquely to the wrest.

The fourth.

His diuision.

The second which is the higher [*tab. 25, fig. 2, char. 35, **] runneth throughout the length of the wand vnto the outside of the Hand [*tab. 25, fig. 2, char. 36, **] and is consumed or spent into two surcles which passe vnto the thumbe, two into the fore-finger and one into the middle finger.

The third [*char. 37, **] descending by the length of the *vlna* or Ell, affordeth surcles to the muscles that extend the fingers [*char. 38, 39, 40, 41, **] and is consumed or spent into the outside of the wrest intrangling with some surcles at the roote thereof [*char. 42, **] the ioynt of the wrest with the cubit.

The fift nerve of the Hand [*tab. 25, fig. 1, and 2, **] taketh his beginning from the foresaid complication, and being fastned to the fourth runneth betweene the muscles that extend and bend the cubite, (yet distributeth no branches to the *Radius* or wand) on the backward and lower side thereof, and when it attaineth to the inner cauity of the proceffe or protuberation of the arme, at the fore side of the cubit it is a little reflected, and affordeth propagations [*tab. 25, fig. 2, char. 43, **] to the muscles which arise from the inner protuberation of the Arme, as also from the Ell and the wand, which muscles doe not receiue any surcles from the third nerve.

The 5 nerve.

From thence passing with a notable branch and being accompanied with a veine and an artery it is fastned to the Ell, and in the middle of the cubit is deuided into two branches [*tab. 25, fig. 1, char. 45, and 46, **] one internall [*char. 45, **] which is conuayed by the inside of the Ell, amongst the muscles that bend the Fingers, and accompanied with a veine and an artery is conducted vnto the wrest, and vnder the transuerse Ligament thereof vnto the palme of the Hand, where it sendeth two surcles to the little finger, two to the middle finger, and one to the ring finger on their insides.

His proceffe.

The other external branch [*char. 46, **] at the middle of the Ell shooteth out a propagation from his outside, betweene the muscle that bends or extends the wrest, which propagation runneth along the Ell, and is lengthned to the outside of the cubit, and at the outside of the wrest bestoweth two surcles on the little finger, two on the ring finger and one on the middle finger. But we must remember that the inner branches are larger then the vter, because the vter may more easily be offended. Sometimes from this fift Nerve there are no surcles distributed to the inside of the hand: sometimes also the outside of the inner part of the middle finger and the inside of the ring finger do obtaine surcles from the third nerve, and then the fift doth onely exhibit two propagations to the inner part of the little finger, and one to the inner part of the ring finger.

The sixt Nerve, [*tab. 25, fig. 1, and 2, **] which in bignesse is answereable; to the second where it attaineth to the cubit, creepeth through the inner and lower side of the Arme and of the cubit as farre as to the hand, [*tab. 25, fig. 1, char. 47, **] and neare the inner protuberation of the arme distributeth many surcles on each side into the skin of the cubit; [*Tab. 25, fig. 1, char. 48, **] which surcles do sometimes lye vnder the branches of the veine, sometimes aboue them, and it determineth not farre from the connexion of the wrest with the cubit [*Tab. 25, fig. 1, char. 47, **]

The sixt.

Here we must note that which we touched before in the 24, Chap. that with the fourth, fift and sixt Nerves of the Hand oftentimes there are mingled certaine small Branches yssuing from the fift Coniugation of the Brayne. And thus much of the Nerves of the Hand.

CHAP. XXXI.

Of the Nerves of the foot in the large acception.

The nerves of
the legge.Their origi-
nally.

He nerves which at the beginning of the legge (by legge we vnderstand here the whole member) doe runne into the thigh and the foot, arise out of the spinnall marrow, out of that part I meane, which consisteth of the spondels or racks of the Loynes and of the Holy-bone; for they are propagated out of the three lower paires of the loynes, and the foure vpper of the Holy-bone; and in their very originall, are mixed like as we said, they were before they entred into the arme, for their coniunction is like the Meishing of a net, or Plashing of a hedge, and so proceed on either side in foure nerves [ca. 26. ch. 57, 60, 66, 71.] they are not all of a like thickeffe, neither is their passage the same, although their common originall be within the cavity of the *Peritoneum* or rimme of the belly. The first and the third are the shortest, and therefore they passe onely vnto the thigh. The second is longer and thicker then they, and reacheth through the thigh into the legge. The fourth is thicker then all the rest, put together and longer also, for it descendeth through the thigh and the leg vnto the ends of the Toes.

The 1 Nerve.

The first [table 26. charact. 57.] ariseth of a commixtion of a branch of the third paire of the Loynes with the fourth paire [about the 22 and 23 racke-bones] and is terminated aboue the ioynt of the knee. This nerve lying vpon the muscles of the Loynes, attaineth to the little *Rotator*, and is consumed into the two extending muscules of the Thigh, and a branch of it into the fore-side and out-side of the skin of the Thigh that lyeth ouer them, but the greater part [char. 59.] affordeth surcles to the first, seuenth, and ninth muscules of the Legge.

The second.

The second Nerve of the leg [char. 60.] issueth ouer against the Coniunction of the third spondell of the Loynes with the fourth, [betwixt 23 and 24.] and being accompanied with the crurall Veine and Artery, passeth through the groines into the Thigh, and descendeth in a notable branch (which on the inside [char. 61.] is fastned to the veine *Saphena*) as farre as to the great Toe passing by the inward ankle. [char. 62.] And this must especially be noted, because of the Section of the ham and inner Ankle-veines, lest if the lancet or Flegme be bent forward, you cut the nerve in sunder: and as the *Saphena* in his descent communicateth diuers surcles, so also is this Nerve diuided into many branches: the chiefe of which is that [char. 63.] which we meet withall about the fore and inside of the knee. The greater portion of this second Nerve [char. 64.] being accompanied with the deepe veine and artery is distributed into the forward muscules of the thigh, especially into the fift of the thigh and the eighth of the leg; yet so, as it disperfeth certaine small shoots into the membranes that there tyethe vessels together.

The third.

The third Nerve [charact. 66.] ariseth especially where the fourth spondell of the loynes is articulated with the fift, and passing ouer the seuenth muscle of the Thigh, it breaketh through the perforation of the share-bone [char. 67.] and reacheth surcles to the ninth and tenth muscules of the Thigh, as also to the muscles of the yard, which arise from the share-bone. It produceth also two Nerves that descend vnto the middle of the Thigh; one of which is sprinkled into the skinne of the Thigh neere the Groyne, [char. 68.] the other is consumed into the second Muscle of the Legge, and into a part of the fift Muscle of the Thigh.

The fourth.

The fourth Nerve [charact. 71, 72.] is sixe times as bigge as the third, yea to say true, of all the Nerves of the whole body it is the thickest, hardest, strongest, and dryest. This is compounded of the foure vpper paires of the Holy-bone, or of the 25, 26, 27, and 28 coniugations. It goeth on the backside of the Thigh, betwixt the *Holy* and the haunch-bones; for where they depart either from other, it runneth into a peculiar cavity or *sinus* of his owne, and first shooteth out surcles from a branch lurking on the backside [char. 72.] vnder the first muscle to the skin, which couereth the buttocks and the backside of the thigh euen vnto the middest thereof. Afterwards, it distributeth other branches on either side, [char. 73.] which for the most part are three, vnto the heads of the third, fourth, and fift muscules of the legge, and the fift of the thigh. Thence forward it is hidden amongst the Muscles, and below the middle of the thigh, sendeth a branch [char. 74.] vnto the fourth muscle of the legge, and sprinkleth propagations into the skin neere the knee. Next in the lower

His diuision,

part

TABVLA XXVI. Sheweth the Nerves of the foot in the large
reception.

From 20 to 24 E. Five paires issuing out of the
Spondels or rackebones of the loynes.

50, 50. Nerves going vnto the muscles of the
Abdomen.

5. Branches from these Nerves vnto the broad
muscle of the arme.

From 25 to 30. fixe paire of Nerves of the Holy
bone.

53 a branch of the paire 25 to the inside of the
haunch bone, and the muscles of the haunch-
bone issuing therefrom.

56 The termination or end of the spinall mar-
row vndiuided.

57 The first Nerue running vnder the Leg or the
Thigh.

58 Branches going from this Nerue vnto the
skinne.

59 Hence also branches going to the muscles
that occupy the outside of the Thigh.

60, The second Nerue of the leg.

61, 62, From this nerue goe branches through
the inner side of the Thigh and the Leg, vnto
the lowest part of the Leg at 62.

63, Surcles from the branch 61 disperfed into
the knee.

64 A branch of the second Nerue running vnto
the depth of the thigh.

65 Hence also a branch vnto the muscle of the
thigh called *Triceps*.

66 The third nerue of the leg.

67 Propagations from this third nerue, vnto the
muscles occupying the hole of the share-
bone.

68 Another branch vnto the skinnie on the inside
of the thigh.

69 A portion of the third Nerue, lying deepe
which goeth vnto the muscles.

70, A portion to the second bending muscle of
the leg.

71, The fourth nerue of the leg which is the thic-
kest of the whole body.

72 A propagation hereof vnto the skinnie on the
backside of the thigh.

73, Another propagation to the heads of the muscles arising from the appendix of the *Cera*. 74, another vnto the
fourth muscle of the leg, and vnto the skinnie that is at the ioynt of the knee. 75, Surcles from the fourth nerue vnto the
heads of the muscles of the foote. 76, the diuision of the fourth nerue of the Hamme into two trunks. 77 The lesser and
vnter trunk of this diuision. 78, 78, A branch of the same trunk stretched vnder the skinnie, and carryed to the outside of
the leg and the foote. 79, the greatest part hereof betwixt the Leg and the Brace. 80, A branch distributed vnto the fore-
of the leg vnder the skinnie from the branch 79, 81, the greatest part of the branch 79, going vnto the muscles of the
foote. 82, The inner and thicker trunk of the fourth nerue of the leg in the arme. 83, A branch creeping along the
inside of the leg and of the foote. 84, a branch of the trunk 82, disperfed into the skin of the Calf. 85, 85, a branch of
the trunk 82 creeping through the forefide of the leg vnto the top of the foote. 86, another branch creeping behind
amongst the muscles of the foote. 87, The remainder of the trunk 82 conuayed downe by the inner ankle, and in his
lower part affording to euery toe two small surcles.

part it disseminateth on either side one surcle, [char. 75.] at the head of the thigh into the
heads of three muscles of the foote. But the trunk it selfe in the backward cavity of the
knee, or in the hamme [char. 76.] is diuided into two branches of vnequall thicknesse, [char.
77, 82.] which are distributed into the whole legge and the foote: for the leg hath no branch
from any nerue, sauing this alone, vnlesse it be a branch of the second paire [char. 61.] which
runneth through the inside of the thigh, the leg and the foote; and yet sometimes a branch
of this fourth nerue is faine to supply the place of that also.

The vnter of these two vnequall branches and lesser [char. 77.] is presently byfurcated;
[char. 78, 79.] and the greater and vnter part of that byfurcation [char. 78.] which is produ-
ced presently about the hamme, descendeth along the Brace and the outward ankle, to the
out-

The vnter
branch.

outside of the foot and the little toe, in his way offering furcles to the skinn: The other and interior part of the byfarcation which sometime also is the greater, [char. 79.] when it hath conuayed a branch [char. 80.] vnto the forepart of the leg, it is hid neere the Brace among the muscles that are called *Peronei*, and affordeth branches vnto them. [char. 81.] From thence it stealeth along, and is returned toward the vtter ankle.

The inner
branch.

The *interior* and greater of the vnequall branches [char. 82.] runneth secretly vnder the muscles along the backside of the Leg, together with the fift muscle of the Foot, and the benders of the Toes seated in the Leg, and being reflected at the backside of the inner ankle, attaineth vnto the soale of the foot, and communicateth most what to each Toe two furcles. This branch is subdivided, and from the greater trunk [betwixt 82 and 85.] a little vnder the diuision, and in the inside thereof issueth a branch at [ch. 84] which is distributed into the skin of the Calse. Afterward the trunk falling into the leg, and stealing vnder the muscles thereof, propagateth yet two branches, one carryed forward, which is greater then the other [char. 85] and passeth through the Membranous Ligament which fastneth the Leg and the Brace together; neare which Ligament it creepeth downeward, affording furcles to the muscles of the Toes to which it is fastned, and passing vnder the transuerse or annular Ligament, together with the tendons of the foresaid muscles, it attaineth vnto the vpper part of the foot, and is distributed into the muscles of the great Toe and those that leade the Toes backward. The other branch which is the lesse, runneth backward, [char. 86] and passeth through the hinde side of the leg, and is consumed into the muscles of the foot amongst which it walketh.

His distribu-
tion.

The lesser trunk [char. 83.] creepeth along the inside of the legge vnto the inner ankle, thence to the inside of the foot, euen vnto the great Toe, and in his progresse sprinkleth diuers furcles into the skin.

Columbus, after he hath made mention of this great and notable nerue, and the distribution thereof, addeth; After the three perforations of the Holy-bone, follow in some bodies the fourth and the fift, out of which doe issue two other coniugations of nerves which after their egress are likewise vnited and beget a nerue, which is reflected and distributed into the muscles of the buttocks and the skin of the same. It sendeth also small nerves into the inside of the *Abdomen*, vnto the muscles of the right Gut; in some men also vnto the muscles of the bladder; in women into the wombe, the necke thereof, and to the muscles of the bladder: others also passe into the *Peroneum* and *Scrotum*, or the Cod. Out of the backpart of the Holy-bone, through his perforations do issue small nerves little and short, which are dispersed into the muscles of the backe, to the buttockes and the skinn of the backside.

The conclu-
sion.

And so haue we brought to an end our History of the Vessels, whose curled streames and wandring passages, if I haue not euery where so exactly troden out, as to giue my selfe contentment: yet I presume that few will be able (if there be any) to find my error. Notwithstanding, I confesse that in two or three places, I haue not been able to comprehend the meaning of my Authours, if at least, they comprehended their owne. Yet I did compare them diligently together; but it is no wonder that in such intricate labyrinths and inextricable Meanders, he that is best acquainted with them, should some time be at losse, in which respect, he that is best able to finde the fault, I hope will soonest pardon the offence.

I proceed in my taske.

The end of the eleuenth Booke.

The Præface.

VR Webbe now weares neare the Threds. The glory and beauty of this stately Mansion of the *Soule* we declared in the first booke. The outward walles we dismantled in the second. The Cooke-rooms and sculleries with all the houses of Office and rooms of repast we suruayed in the third. The Geniall bed and the Nursery we viewed in the fourth and fift. In the sixt we were ledde into the rich Parlor of pleasure, wherein we were entertained by a leuy of Damozels; one *Modest* as *Modesty* it selfe: another *Shamefast*, another *Coy*, another *Jocond* and merry, another *Sad* and lumpish, and a world of such *Pastions* we found inhabiting in the *Little world*, there also we saw the curious clocke of the heart mooued by a perpetuall motion; the Heralds of honor, those nimble and quicke Pursuants, those agile spirits whose presence giues life, whose pleasance giues cheere and refreshment whither soeuer they are sent. From thence we ascended in the seuenth Booke by staires of Iuory into the presence Chamber, where the *Soule* maketh her chiefe abode; there we saw the Councell gathered, the Records opened, and Dispatches made and signed for the good gouernment of the whole family. From thence in the eight Booke we clombe vnto the battlements, and saw the watch of the Senses set to discouer and giue warning of the approaches of enemies. In the ninth we obserued the guard appointed to fetch in the prouision from without, to entertain or giue the repulse, to defend or offend as cause required. In the tenth wee discouered the Materials which filled vp the empty distances in the walles, and parted the rooms asunder. In the eleuenth we followed the courses and conuayances, the entries and Lobies which leade throughout the whole edifice from chamber to chamber, out of one office into another. Now we are arriued neare the principals of the building, where we may see how they are ioyned, how they are fastened and bound together, how they are couered and defended, how they are interlaced and intertexed. And finally, in the next and last booke we shall (with God to friend) come vnto the Principals themselves and to the very foundation and ground-worke whereon the whole Frame is raised.

The first part, of Gristles.

CHAP. I.

Of the definition, use, and differences of Gristles.

BEfore we come vnto the particular Histories of the Gristles, it will be requisite to speake something in generall which may open their nature, vses, and differences. A Gristle therefore is a similar part, cold and dry, made out of the thickest part of the seed gathered together by the power of heat, and ordained to secure the variety of motions, and to put by outward violence. That it is similar is very manifest, because it is altogether of the like it selfe, the least fragment or particle thereof retaining the nature, temper, and name whole.

This Gristle, if we will beleue *Galen*, is to be numbred in the list of those parts which are gouerned by themselves and do not gouerne others. It is cold because the heat soone vani-

The definition
of a Carti-
lage.

The explicati-
on of the de-
finition.

sheth

sheth away, and dry for that the moysture is vapoured from it, whence also it becommeth hard but not so hard as a bone.

The matter of it is the crassament or thickest part of the seede. The efficient is heate, which is the immediate organ of the procreating Faculty, to which the *Altering* and the *Forming* vertues are assistant: yet is not this an extending heate, such as whereby the Membranes are dilated; nor perforating, such as boreth the Veines and Arteries, but a more remisse degree with gathereth or curdleth the parts together, and is indeed proportionable to cold in outward things, there being nothing actually cold in a liuing body. But as a high degree of heate doth melt the Lead which caketh when it is lesse hotte though a great heat do remaine yet in it; so it is in the body, the greater heate diuiderth the parts and the lesser gathereth, or if wee may so say, congealeth them.

The finall cause is expressed in the last particle of the definition, for although there be diuers uses of Gristles as we shall shew by and by, yet these two are principall. First, to make the ioynts of the bones which are coupled by *Diarthrosis* more gladde or easie to moue, and more secure and permanent. Secondly, to defend the parts vnder them from outward impressions or iniuries.

The Nature of a Gristle is not much vnlike that of a bone; for saith *Aristotle*, when the bones are in any creatures wanting, the supply is made by Gristles. Their Tempers also are not farre asunder. Sense they haue none, because the creature should not be in perpetuall paine, neither indeed haue they any Nerues dispersed through them. Notwithstanding as we shall say in the next Booke there are some kinde of bones which haue Sense, the teeth for instance; So some Gristles seeme to haue Sense, as those of the Eye-lids, because certaine small Tendrils of Nerues do touch them.

Finally, saith *Laurentius*, a bone and a gristle do differ but *secundum magis & minus*. For bones are harder, drier and colder: yet we may say further, that all Gristles are transparant, smooth and polished, many bones vnequall and sharpe. Moreover, a Cartilage or gristle hath no marrow, nor cavity, nor corners, or celles in it as bones haue, because there was no need of them, for being not so thick or solid as a bone their aliment doth easily passe through their substance. We conclude therefore, that a gristle is of a middle nature betwixt a Bone and a Ligament, faster or thighter then a Bone and harder then a Ligament.

How Gristles
and Bones doe
differ.

The uses of
the Gristles.

The first,

The uses of the Gristles are diuers and those very admirable and wonderfull. The first and most common vse is to helpe the motion of the bones which are ioyned with a laxer or loose articulation, for by the helpe of the Gristle the motion becommeth more easie, more secure and more permanent. More easie, for being smooth and polished, it leuigateth and maketh slipper the asperities or roughnesse of the bones, and so their heads become more glib or prompt in their motion. Whence it is that all moueable ioynts are crusted ouer with a Gristle: So also are the heads, and the *sinus* or cups or cavities of bones where they touch one another lined with a smooth gristle. They make the motion more secure, because the gristle encreaseth the hollownesse of the bone that so the articulation is not so easily luxed or put out of ioynt, as we may see in the articulation of the arme with the shoulder-blade, and in many others. Finally, by the inter-vening of the gristle the motion is preserued and made more lasting and dureable, for the extremities or ends of bones being very hard by their mutual contraction and perpetual attrition would haue been worne and fretted, and so in time the motion would haue decayed, which inconuenience is auoided because they are compassed or lined ouer with a soft gristle.

The second.

The second vse of Gristles is by yeelding to illude or breake the occurrance of outward iniuries, as when the bones are beaten or ratled together, or some other violence offered, which haply might breake a bone: for being of a middle nature betweene very hard and very soft, it cannot be easily broken, as that which is hard and friable or brittle, nor easily wounded or bruised, as that which is soft and fleshy.

By-vses of
the Gristles.

Hence it is that the Extremities of many bones which are exposed to external offence haue gristles allowed them, as the Nose and the Eares. And these are the chiefe and primary uses of gristles: there are also many other by-vses, as some gristles like bones do sustaine some parts, some haue muscles affixed vnto them, and some do sustaine or establish the vessels. Such are the gristles of the *Larynx* or throtle and the rough artery, as also those of the eye-browes, into which as into a pale the beard of haire whereby the eyes are defended, are infixed.

The fourth.

There is also a fourth added, as if they should be defences or muniments to safeguard the parts subiected vnder them. So the gristles of the brest-bone and the ribs were made for the

the defence of the heart and of the lungs, although they make indeed the motion of the chest more easie, because they follow with more readinesse then bones would, his distention and contraction. In like manner the sword-like cartilage which we call the brest blade is thought to haue bin ordained to defend the midriffe & the mouth of the stomach when it is distended.

A fift vse of the Gristles you may gather out of *Galen* his booke *de ossibus*, that by their mediation as it were by a glew some bones might be conioyned. So the share-bones are vnited by a Gristle, and that kind of coniunction is called *Synchondrosis*. The fift.

I will adde also a sixt out of *Galen*s eleuenth booke *de vsu partium*, to ioyn hard and dense bones with lax and rare, for it filleth or maketh vp the hollow holes of a rare or lax bone, and leuigateth or maketh smooth his rough sharpenes. The sixt.

Finally, there are other and those very many peculiar vses of particular Gristles. Some belonging to the sight, some to hearing, some to smelling, some to digestion or swallowing, some to respiration or breathing; some to apprehension and some to progression, as partly hath bene and shall further be declared in the History. Many peculiar vses.

For the differences of gristles they are to be taken from their substance, magnitude, figure, site, vse, and connexion. From the substance or rather from those things which follow the substance, that is, hardnesse and softnesse; some gristles are hard which at length become bony as those that forme the *Larinx*; others are in a meane which doe neuer degenerate into the nature of a bone, as that which we call the *Epiglottis* or *Ouer tongue*; others are soft which tye the ioyns together & carry in them the nature of a ligament, & such are called *Χονδροσύνδεσμις*. From the magnitude; some are great and others are small. From the figure, which is very diuers, Gristles haue diuers names, as *Ensiculata*, *Annularis*, *Scutiformis*, *Aritenoides*. The blade Gristle, the ring Gristle, the shield Gristle, the ewre Gristle. From the site, some are called vpper, some lower, some fore, some after, some internall, some externall Gristles. From the vse we may also gather differences and varieties of Gristles. Some are made for motion, some to auoyd outward iniury, some for defence and some onely for supportation. The differences which are taken from Connexion are more necessary and therefore a little the more to be stood vpon. A gristle therefore either groweth to a bone or maketh a part by it selfe. That which tyeth two bones together, either doth it by the interposition of common ligaments, as it is in the end of bones that are connected by *Diarthrosis*, or immediately as in the share-bones and the brest-bone. That which is fastened to a bone appeareth in the gristle of the Nose, in the brest-blade and that which groweth to the *Coccyx* or the Rump. The gristle which maketh a part by it selfe is by some called *Solitaria*, such is the gristle in the extremity of the Eye-liddes, such are the gristles of the *Larinx* or Throttle; of the rough artery, of the outward eares and of the *Epiglottis* or Ouer-tongue. The differences of Gristles.

But for more perspicuity we wil referre the whole history of the gristles vnto three heads. Those of the head, those of the trunk, and the gristles of the ioyns: the gristles of the head are, of the Nose, of the Eares, of the Eye-lids and of the lower Jaw. The trunk is diuided into the Spine and the Chest. The parts of the spine are the necke, the backe, the loynes, and the holy-bone. The gristles of the necke are either behind or before. Behind, those that tye the spondels together; before, the Throttle, the Rough artery, and the Ouer-tongue. The gristles of the chest are those in the extremities of the ribs, and those of the brest-bone. The gristles of the ioyns are some of bones receiuing, some of bones receiued, and of each of these some belong to the Hand and others to the Foote. Now we descend to the particulars. A diuision of Gristles.

CHAP. II.

Of the Gristles of the Face.

F the Eye-lids we haue spoken before in the third chapter of the eight booke which we will not now repeate, onely heere remember that a great part of them are cartilaginous or gristly, by which the opening and shutting of the eye is made equall, by which the violence of outward iniuries is better resisted, and in which the small haire that keepe dust and flies from the eyes are infixed and sustained, which otherwise would haue fallen if the lid had bene onely made of flesh and membranes. The Gristles of the eye-lids.

Againe, if they had bene bony, they would not haue bene so easily moued, and beside, their hardnesse would haue offended the coates within the eyes which are of exquisite sense. But this gristle is very thinne that it might be a little transparant to cast a little shadow

dow of the externall light vpon the eye. There are two of them, one vpper, and another lower; the vpper is greater in a man, and in those creatures whose lower eye-lids are im-moueable, or their motion (if it be any) very little and obscure, whereas in Birds the gristle of the lower lid is the greater. They are called *ragodi*, because the row or beard of haire, which is set in so many perforations made in the gristle, are not vnlike a ranke of rowers in a Gally. There is also another gristle in the greater angle of the eye, which hath the figure and vse of a Pulley, described elegantly at the first by *Falopius*. This Pulley hath a Canale or open perforation through which the tendon of the muscle that moueth the eye round is conueyed, but of it we haue spoken before. In the ioynt of the lower iaw there is a slippery and moueable gristle which interposeth, lest the bones of the temples, and the iaw should by their mutuall attrition be worne, or when they are wearied with too much labour giue ouer their motion.

Of the out-
ward eares.

The outward eares called in Latin *Auriculae*, are also gristly, for if they had bin bony they might easily haue bin broken, and beside would haue bin an impediment in our sleepe.

Againe, if they had been soft and fleshy, they would not haue retained their arched figure, and so the ayre should haue bin shut out, or if it had bin admitted, a fleshy substance could not haue repelled the sound. These gristles are aboue, thicker & harder; below, thinner and softer till you come to the lap which is of mixed nature betweene flesh and gristle.

Of the nose
are five.

The gristles of the Nose are five, the three anterior are fastned to the circumferences of the bones, and two make the wings.

Of these the two vpper are the broadest and adhere to the bones of the Nose [*tab. 12. lib. 8. fig. 8. from f to e*] where they are broad and rough. From them they hang, and together with them doe forme the anterior cauity of the nostrils and their lower part. Descending downward they run out being fastned together vnto the tip or top of the Nose, and the lower they goe, the softer they are, in the very extremity degenerating, as it were into a gristly ligament. The third gristle, which is in the middest betwixt these two is called *Septum cartilaginofum*, the gristly partition, which groweth to the bony partition, for it depending forward groweth to the foresaid gristles throughout their length on the inside. This is the gristle which maketh the Nose to rise in the face, and distinguisheth the two nostrils, where also the bony partition aboue the region of the Pallate, separateth the perforation of the nostrils from the Nose vnto the Chops. To these three gristles, other two are annexed which make the wings of the Nose called *ala* or *pinna*, because like wings they shut and open the nostrils, and they are tyed with membranous ligaments to the former gristles on their inside. Each of these gristles is orbicular, and so make the holes of the nostrils round, and indeed they approach neare vnto the nature of a ligament.

Their vse.

Moreouer, they haue voluntary motion, being drawn vpperward and downward, inward and outward by proper and peculiar muscles, and in great inspirations they are a little eleuated, but in expirations doe settle againe. They are seated in the lower part of the Nose, for the vpper is bony to be a foundation vnto the rest: but it behooued that the lower part of the Nose should be gristly, partly that the cauities might remaine alwayes open for the better attraction of the ayer into the Lungs, and into the braine; partly that being soft, wee might close our noses against any euill fauours, partly also the better to euacuate the excrements of the braine through the nostrils; and finally that they might yeeld to outward violence, to which they are most of all exposed. This part of the Nose if by any casualty it shall happen to be cut off, may be elegantly restored by a *Traduction of skin out of the arme* as we shall (God willing) at large discourse and exhibite the figures of that kinde of deligation in our worke of Surgery. And so much concerning the gristles of the Face.

CHAP. III.

Of the Epiglottis, the Gristles of the Larinx and of the Weazon.

Epiglottis.

F the *Epiglottis*, the gristles of the Throttle, and the Weazon wee haue spoken before in the eighteenth chapter of the sixt booke, and in the 34 and 36 chapters of the eight booke; wherefore here it shall be sufficient to touch vpon them and so to passe vnto the rest that follow. You must therefore remember that the *Epiglottis* is nothing else but a gristle that lyeth vpon the cleft or slit of the *Larinx* made

of

of the two processes of the Ewre gristle. The forme of it is compared to an luy leafe, whose basis is broad but the cone not very sharpe. The basis is in the vpper and inner side of the shield gristle, the cone vergeth toward the Pallate. If this gristle had been bony, it would not so easily haue been depressed in deglutition, nor readily againe lifted it selfe vp for the inspiration of ayer. If it had been fleshy or membranous, it would indeed haue easily fallen but not so readily risen againe. The vse of it is double. The first to couer the Larinx, that in swallowing the meate and the drinke might not passe into the Lungs, for the gullet lies behind the wind-pipe. The second vse is to breake the ayer that is driuen out of the Lungs and to Modulate the voyce.

This gristle saith *Laurentius* standeth alwaies yawning open, as well when we draw in our breath as when we breathe it forth. Neither is it at any time depressed of it owne accord but onely by the weight of the meate and drinke which wee swallow, neither at that time is it so exquisitely closed vp but that a portion of the drinke sipeth by into the rough Artery.

As the *Epiglottis* is the couer of the *Larinx*, so is the *Larinx* the head or couer of the Rough artery. The whole body of it is almost all gristly, for being the Organ of Breathing it was necessary it should euer be open whether we had need to take in fresh ayer or to breathe out old.

Againe, it is the Organ of the voyce which is nothing else but a percussio of the ayre, Now the ayer is not broken but at a solid, hard, and light body. It consisteth of three gristles or rather of foure, which are so fastened together that by them it may easily be dilated and constringed: shut and opened. The first is called *Thyroides* the shield-gristle, because it is like a square shield such as is carried before Tilters in their triumphs; and this is sometime double, especially in women, in whom likewise it buncheth not out so far forward as it doth in men. The second is called *Crycoides* the Ring-gristle, for it is wholly circular and keepeth the pipe open. It preuenteth also the compression of the rest of the semicircular gristles in the motions of the Larinx. The third is called *Argyranoides*, or the Ewre-gristle, because it is like an Ewre with which we vse to powre water vpon mens hands, or rather it hath this denomination from the similitude it hath with an oyle cruise.

The first Anatomists accounted this gristle single, but those that haue come since haue found it to be double, and that the parts thereof are connected or knit together with membranes or with ligaments. And indeed these parts thus ioyned do make the *glottis* or cleft of the Throtle. The opening or closing of these parts make the voyce base or treble, but the *Epiglottis* striketh a great stroke in it as it shurteth his cleft more or lesse. *Columbus* saith that these gristles do sometimes turne to be bones and instances in a notable Fellow who could not be hanged. And thus much of the Larinx, now we proceede to the rough Artery.

The *Weazon* because it is a vocall Organ or wind instrument, fistulated or made hollow to leade ayer vnto the Lungs and to returne out of them fumid vapours the recrements of the spirits, it was for the greatest part made of gristles, and thence it is called *καρχία*, *Arteria aspera* because it is asperated or made rough and vnequall with gristlie rings. Now a gristle is the fittest instrument of the voyce because it is of a middle nature betwixt hard and soft, for soft things because of their weaknesse do strike the ayer more remisly, and hard things doe easily ouerturne it.

These gristles are like rings, not round rings, for on the backpart where they touch the gullet they end into membranes, so that they are but semicircular like the letter C, from whence also they are called *αργυροειδεις*. These gristles saith *Laurentius* doe not onely runne as far as the Iugulum as some haue dreamt, but throughout the whole course of the artery they are in all his branches that passe into the whole flesh of the Lungs, an obseruation which few men haue made triall of.

The reason why these gristles were not made perfectly circular, I thinke was, as well that the Gullet should not be hurt with the hardnesse of the artery, as also that we might swallow the more freely, for oftentimes we swallow hard and vnbroken bites which would out of doubt offend vs vnlesse the artery did yeeld vnto the Gullet.

It may be objected that the body of the Larinx or Throtle is wholly gristly, and yet it hindereth not the Gullet.

But there is a great difference betwixt these, for in deglutition er swallowing the Gullet is drawne downward but the *Larinx* runneth vpward, so that the situation of those

The gristles
of the Larinx.

The Weazon.

Why gristly.

Why the
rings are not
round.

parts is changed, and the beginning of the Gullet approacheth vnto the rough artery, but the throttle ascendeth as high as to the chops.

Moreouer, these gristles are semicircular, onely in the vpper part, as low as in the *Ingu- lum*, but when they are past the *Oesophagus* and come vnto the Lungs, they grow round, because it was necessary that the artery in the Lungs should be kept open for the freer tra- cion and expulsion of the aire. He that desireth further satisfaction concerning the nature of these gristles, let him repaire to the 18 chapter of the first booke.

CHAP. IIII.

Of the Gristle in the Trunke or Bulke of the Body.

The gristles
of the Spine.

He Gristles that are in the Bulke of the Body, are either in the rackebones of the Spine or in the Chest. In the Spine there are many Gristles to establish the articulation of the Spondels, and to make their motion more facile and easie. All the *vertebrae* of the necke haue Gristles aboue and below, excepting the first, so is it likewise in the backe and in the loynes. But those of the Holy bone are harder and dryer then the rest, because the whole bone is immouable.

The extremity also of the Holy-bone is gristly, and is called *Coccyx*, or the Rumpe. It carryeth the figure of a Corner, or paper, wherein Grocers vse to put vp their Spices, sa- uing that the cone or sharpe end is somewhat beaked or crooked. This establisheth the right gut, as also the necke of the wombe and the bladder, and when women are in travell, it is bent backward, not without very great paine.

Of the gristles
of the Chest.

For the chest it behoued well that some part of it should be gristly, that it might more follow our inspiration and expiration. First therefore there are two gristles which ioyn the clauicles to the brest-bone. Then the *Sternum* or brest-bone hath a gristle in the vpper, and another in the lower part. In the vpper part betwixt the first and the second bones which serueth instead of a ligament, but below appeareth that notable gristle which they call *Xiphoides*, or the brest-blade. The forme of this gristle is very diuers, for it is not alwayes acuminated or pointed; but sometimes broad in the end, and sometimes tynd or diuided into two forkes, and thereupon some haue called it *Furcella* the little *Forke*. Of- tentimes, saith *Laurentius*, we haue seene it round like the *Epiglottis*. Sometime the parts are vnequall, and the lesser lyeth ouer the greater, like the leafe of the herbe which we call Horfe-tongue, about the middle of it, it is perforated with a small hole which few haue obserued, made to transmi a nerue and a veine.

The brest-
blade.

The vse of it.

The vse of this gristle is the same with other gristles which hang at the ends of bones, to wit, by yeelding to breake the violence of outward iniuries, and to defend the parts subie- cted thereunto. Some thinke it was made as a defence for the midriffe which in that place is nervous; some to safegard the mouth of the stomack; hence say they, often comes a *Nau- sea*, or loathing of the meat, when this gristle is bent inward and presteth the mouth of the stomack. Some of the *Neotericks*, or new writers, do deride this latter vse, because say they there is a great distance betwixt this gristle and the mouth of the stomack, which is appli- ed to, or leaneth vpon the back; but *Laurentius* saith, it is false that there is any such distance in living bodies, for first, they that vomit much when they are about to cast, doe find a paine at this gristle.

Againe, *Hippocrates* in the third section of his booke *De Articulis*, hath remembred such a distention of the stomacke, to the foreparts where he saith, *That the repletion of the belly* (he meaneth the stomacke) *is a direction for broken ribbes*.

Moreouer in *Coacis*, he calleth the mouth of the stomacke *Sternum*, where he speaketh of the bitternesse and gnawing of the *Sternum*, that is, of the mouth of the stomacke; but aboue all, that is absurd, and an old wifes fable, who say that this gristle sometimes fals away and may be replaced againe by muttering a peece of the *Mattens* ouer it, and by attraction or groping vpon it.

Two gristles
in each rib.

Finally, euery rib hath two gristles, one on the backe-side where it is articulated to the spondell: another on the fore-side, by which it is ioyned to the brest-bone. But the for- ward are greater and thicker then those that are backward, because the fore-part of the chest is distended and contracted. The gristles also of the bastard ribs are longer then those of the true ribs. And so much for the gristles of the trunke.

CHAP. V.

Of the Gristles of the Ioynts.

Here is almost no Ioynt in the whole body of Man, but for his more-secure and facile motion, it is crufted ouer with a Gristle, as partly we haue shewed before in particular. Moreouer, in the cavity or hollownesse of the shoulder-blade, Nature placed a Gristle to increase the *sinus* or bosome of the bone, lest in violent motions the ioynt should be easily luxed or put out.

In the lower part of the Cubit which hath an acute or sharpe processe, there appeareth a gristle which filleth vp the empty distance. It hindereth the hand when it is led to the side from offending against that acute processe. Betwixt the share-bones there is a thicke and hard gristle so vniting them together, that it is not credible they should be seuered in the time of trauell, as we haue shewed before in the 33 Question of our first book. In the cavity of the hanch-bone there is another gristle which increaseth the compasse of the bosome or cavity therein.

Finally, in the lower heads of the thighes we finde two semicircular gristles which enlarge the lips of the cavities. In a word almost euery articulation is crufted ouer with a gristle to make the motion more easie, more secure and more permanent: and so much concerning Gristles. Now we proceed vnto the Ligaments.

The second part of Ligaments.

CHAP. VI.

Of the Nature, vse, and Differences of Ligaments.

As the lubricity of Gristles makes the motion of the Bones more nimble and quicke: so the Ligaments doe secure both motion and articulation: but there is a double acception of a Ligament, the one large, the other presse and more restrained. In the first sense we call any thing a Ligament, which tyeth one part to another. So Hippocrates calleth the skin and the flesh *colligations*, the ancients also called all manner of vessels, veines, arteries and sinewes, *common Ligaments*. In the presse and strict signification we call that a Ligament which is a hard and firme body, yet lax and flexible and without sense, which incompasseth, tyeth downe and containeth the ioynts.

This kinde of Ligament properly so called, the *Grecians* call *σύνδεσμος*, the *Latines* *copula*, *vinculum* & *Ligamentum*, we may call it a Tie; but because the word Ligament is grown into common vse, we will, if you please, retaine it for the most part. *Laurentius* giueth this definition of a Ligament. It is a similar cold & dry part, of a middle nature betwixt a nerue and a gristle (betwixt a membrane and a gristle, saith *Banrhine*) ingendred by the power of heat out of the slimy part of the seed, and being of great vse in colligation, containing, inuesting and forming of muscles.

Concerning the temper of a Ligament (which is the forme of a similar part) all men doe agree. It is cold and dry without question, albeit some peculiar ligaments of ioynts, are lined ouer with a mucous and slimy humour; but concerning those things which accompany, follow, and happen to the temper, many haue made scruple: hardnesse and softnesse follow the temper, sense and motion happen vnto it. We resolute that Ligaments are of a middle nature, betwixt gristles and membranes: harder then membranes, lest in vehement motions they should be broken, and softer then gristles, that they might more easily follow and obey the muscles which moue the bones. For the most part they are all insensible, as well because they receiue no nerues into them, as also lest being perpetually moued they should breed perpetuall paine.

It may be obiected, that *Galen* in his third booke *de facultat. natural.* saith, that Ligaments consist of sensible fibres; but we must know that by *sensible*, in that place, *Galen* vnderstandeth not that which hath sense, but that which is liable to sense, not that which is sensatiue but that which is sensible. For Ligaments borrow nothing of the braine, and therefore haue no sense, neither can they moue themselues; notwithstanding as among the bones, the teeth haue sense, among the gristles those that make the eye-lids; so amongst the Ligaments there are some which haue the sense of touching, as the two ligaments that make the yard, and the reyne or bridle of the tongue.

A double acception of a Ligament.

The definition of a Ligament.

Obiection Solution.

The matter
of Ligaments.

The matter of Ligaments is the slimy part of the seed extended or lengthned by heat, whence it is that they can be contracted and againe relaxed. Their Aliment I doe not take to be (saith *Laurentius*) as some would, marrow, but bloud conuayed vnto them by *Capillary* veines, which are so little that they cannot be perceiued.

Their vses.

The vses of Ligaments are diuers, the first and most common is to firme and assure the articulations, especially those that are more laxe of the bones and the gristles and to hinder luxation, for it was to be feared that when the bones are separated in violent motions they should be also distracted, vnlesse the wisdom of Nature had provided to tye their extremities together with strong and strait bonds. These Ligaments which performe this vse are either common which compasse the ioynt round about, or priuate. The common are thin and membranous, the proper are thicker and most what round.

2 Their second vse is to bind and fasten the bones where they are not articulated, for there are thinne and fine Ligaments which tye the cubit to the *Radius* and the Legge to the *Brace* where they gape asunder, as also the spines of the spondels.

3 The third vse is that which *Galen* remembreth, who saith they serue for an outward garment to defend the tendons. So the tendons which bend and extend the Fingers and the Toes are throughout their whole length covered with Ligaments and with membranes.

4 Adde hereto the fourth to containe the Tendons in their owne places, to establish them and safely to transmit them from one place to another. Such are the Transuerse Ligaments of the wrest, round like a ring and therefore called *Annularia*.

5 Fiftly, they are interposed like a pillow betwixt the bones and the Tendons, that the hardnesse of the bone should not offend the tender and sensible tendons.

6 Sixtly to discriminate or separate the right muscles from the left, the fore muscles from the hinder, and other parts one from another, as we may see in the Ell and the *Wand*, in the Leg and the *Brace*.

7 Seauenthly, to encrease and augment (as do the gristles) the *Cups* of the bones.

8 Eightly, to suspend the bowels that they should not fall with their great waight. Such are the Ligaments of the Liuer, the Bladder and of the Wombe.

9 Finally, they concurre vnto the structure of a muscle, for of the fibres of a nerue and a ligament mixt together is a tendon made.

The differences
of ligaments.

The differences of Ligaments are to be taken from their substance, magnitude, figure, site, originall, insertion, vse, and from their principall parts. From the substance some are soft, some hard, some membranous, that is, like vnto membranes, because they be broad. Some are neruous, that is, round like nerues; some are gristly. From the magnitude some are little some are great, some are broad and some are narrow. From the figure some are broad some are round, some are continual, some are proforated, some are transuerse and annular, and some are long and direct. From the situation they are supernall infernall, right left, fore and backe Ligaments.

From their originall and insertion their diuision is very elegant, some arise from bones, some from gristles, and some from membranes. Those which arise from bones are inserted either into a bone or into a gristle, or into the heads of muscles, or into some other part. Of those which arise from a bone and are inserted into a bone, some do firme the ioynts, others tye the two bones together without a ioynt, others defend and inuest the tendons. Those which arise from a bone and are inserted into a gristle doe appeare in the knee, one from the internall roote of the inner *Cup*, the other placed vnder it. Those that are inserted into the heads of muscles are very diuers, some grow out of bones and runne into other partes, as that double Ligament which maketh the greatest parr of the yard, and ariseth out of the share-bones. Those Ligaments that arise out of gristles are some of them inserted into gristles; such are they that tye together the gristles of the *Larynx*; they that are in the end of the Rump and those that tye together the halfe circles of the Rough artery; others are inserted into the heads of muscles, as those that runne into the vpper muscles of the *Larynx*. Those Ligaments that arise from membranes are but few.

From the vse you may gather diuers differences of Ligaments according to the vses before named.

Finally, from the principall or more notable parts of the body we may very fitly deuide Ligaments into those of the Head, those of the Chest and Backe, and those of the Ioynts, according to which diuision we will now prosecute their particular History.

CHAP. VII.

Of the Ligaments of the Head.

He Ligaments of the Head doe some of them belong to the whole Head, some to particular parts thereof: the whole Head is moued about the first and the second *vertebra* or spondell of the necke, wherefore it was needfull that it should be fastened with strong ligaments, otherwise a notable part had been in danger of luxation. Of these Ligaments *Bauhine* reckoneth foure, *Laurentius* but three, which notwithstanding (saith he) may be diuided into more particles.

The ligaments of the head.

The first is a very great and broad Ligament which tyeth the first racke-bone vnto the Head and compasseth the whole ioynt round about. It hath two portions, one like a thicke membrane, and runneth to the inside of the first spondell, the other part compasseth about the outside of the ioynt. It ariseth out of the *Basis* of the *occiput* or Nowle of the Head, which is therefore exasperated, and in yong children is scotched or cleft manifold: hence it is, that the first and second *vertebra* may sooner be broken then luxated.

The first.

The second Ligament fastneth the proesse of the second Rackebone called the *Tooth* to the head, and it consisteth of three parts. Two arising from the outside of the *Tooth*, are inserted into the inside of the circumference of the hole which is in the Nowle-bone. The third is round like a nerue, and ariseth from the foreside of the *Tooth*, and is infixed likewise into the hole of the Nowle, to which it adhereth very strongly.

Second.

The third Ligament is very like a nerue and made with wonderfull art, and compasseth the cavity of the first Rackbone which was made to receiue the *Tooth* of the second, and constringeth the said *Tooth*, so firming it that it cannot incline to either side; it safeguardeth also the spinall marrow, lest it should offend against the bare bone.

Third.

The fourth Ligament ioyneeth the second Racke-bone to the first. It is membranous and of the same nature and vse with the other ligaments of the ioynts; and these are the common ligaments of the head. There are also other proper ligaments in the head, which belong to particular parts: as the ligament of the gristle of the Eare: a strong ligament, for it fastneth the root to the stony-bone, and ariseth with diuers propagations from the *Pericranium*, where it tendeth toward the *Mammillary* proesse. These propagations when they come vnto the eare doe grow together into one ligament, and it is inserted into the vpper and gibbous part of the eare to hold the gristle pricked vp and suspended.

Fourth.

Of the ligament of the eare.

There is a ligament also in the eye, called by *Falopius*, *Ligamentum Ciliare*, not because it is of the nature of a ligament, but because the grapy coat is thereby fastned to the verge or circumference of the membrane of the *Christalline*, but we haue spoken of it sufficiently before in the end of the seuenth chapter of the eighth booke.

Of the eye.

The Ligaments of the vpper law, betweene the *sutures* and the *harmonies*, are thinne and membranous, made for the originall of the muscles, for from them the tendons of the muscles of the Face and of the neighbour parts take their originall. The articulation also, (saith *Galen* in the 20 chapter of his first booke *De usu partium*) of the lower law with the Temple-bones hath strong ligaments, which *Bauhine* out of *Platerus*, calleth a common membranous ligament incircling the whole ioynt.

Of the law.

The ligament of the tongue *Galen* discourseth of in the 10 chapter of his 11 booke *De usu partium*. It is strong, membranous and broad, but of it we haue spoken before in the 32 chapter of the 8 booke. Of the ligaments of the bone *Hyois*, we shall speake in the booke of Bones. Of the ligaments in the Heart, in the rough Artery and the cutany ligament of the wombe, we haue spoken before in their proper places, which we will not now stand to repeat, but proceed on vnto the ligaments of the Spine and the Chest.

Of other parts.

CHAP. VIII.

Of the Ligaments of the Spine and the Chest.

He motions of the Spine are very diuers, and therefore the Rackebones stood need to be fastned together with ligaments. In these Rackbones we may obserue their bodies and their proesses. In like manner there are two sorts of ligaments, one kind fastneth the bodies of the spondels, another their proesses, and these saith *Bauhine* are of two sorts, the one is strong and mucous, which compasseth the bones and fastneth the whole length of the Spine; in violent motions downewards, and in great burthens securing it from danger.

Ligaments of the Spine.

The

The other sort is gristly, and *Galen* indeed in his Booke *de ossibus* calleth them Gristles, which kind goeth betwixt the bodies of the spondels and fastneth them strongly together. It is fibrous and mucous, thicke without, but toward the middest attenuated, and carieth the very forme of the spondell, answerable to it in breadth and length, and determineth into the gristle which is betwixt the spondels. The ioyntes of the processe are also fastned with common membranous ligaments, the ascendents with the defendents. Furthermore there is another priuate or particular Ligament and yellowish, arising out of the inside of the hole of the Rack-bone at the roote of the backward processe betwixt two ascending or descending processe, and is againe inserted into the same place of the subsequent spondell.

In the necke of a Dogge we meete with a Ligament which is rare indeed but strong and yellow, and cannot be parted into fibres. It groweth out of the very top of the spine of the seventh Racke of the necke, and ascending vppward free and at liberty is fastned into the top of the second spine of the necke. In sheepe it groweth to the Nowle-bone. In beastes of burthen it is very thicke for more strength, and of all the Ligaments of the body is refused for meat; yet saith *Vesalius* some commend it to be eaten to make the haire grow long. It may be (saith he) because it is easily dissolved as it were into yellow haire. In some creatures throughout the length of the backe runneth a Ligament on each side betweene the muscles that moue the backe, which saith *Vesalius*, *Galen* also attributes to men in his booke *de usu partium*.

Of the Chest.

The Chest also hath his Ligaments for all the ioynts thereof are ioynd with common membranous Ligaments compassing them about. So the ribbes are fastned to the spondels with strong and almost gristly Ligaments, especially the first and second rib because of the burthen which they were to beare; likewise the twelfth, because it is not sustayned with a transuerse processe. The same ribs are ioynd by the mediation of Ligaments of the gristles of the brest-bone. The bone also of the Brest it selfe is fastned to the clauicles by the interposition of a proper Ligament.

CHAP. IX.

Of the Ligaments of the Shoulder-blade, the Arme, the Cubit, and the wand.

THE head of the Arme being round that the whole Hand might moue speedily every way, & the cavity or *Cup* of the Blade being but shallow; (as whose browes are narrow) least in the diuers morions the Arme should be luxed, Nature partly by two recurued processe of the blade, partly by Ligaments which defend the ioynt, hath provided for so desperate an inconuenience.

Five ligaments of the arme.

These Ligaments are five. The first is *Broad*, so *Galen* calleth it, and membranous like the Ligaments of other ioynts. It taketh his originall circularly out of the verges or browes of the necke of the Blade, incircleth the whole ioynt about, and is infastned on the inside of the beginning of the head of the Arme, and implanted into the outside of the head and into both their neckes.

The second is perfectly round, as also is the third, and groweth from the top of the *interior* processe of the Blade, and compasseth about the inside of the vtter head of the Arme whereto it groweth very strongly.

The third is thicker and greater then the former and ariseth out of the vpper part of the necke of the Blade, and climbing over the head of the arme, is inserted into the outside thereof, where at his cavity the outside buncheth out somewhat, so that these two Ligaments together make as it were one transuerse Ligament.

The fourth is broad also and issueth out of the same place with the third. His originall is large, and runneth obliquely till it be infixed into the backside of the vtter head of the Arme where it compasseth the backepart of the ioynt as did the first.

The fift issueth from the *anterior* processe of the blade and runneth vppward to the top of the shoulder.

The vse of these Ligaments is; of the first the same with the Ligaments of other ioynts; of the three next to keepe the arme that it fall not downeward or outward out of his socket. Of the fift to keepe the arme from luxing forward, in which seruice it is holpen by the outward head of the double headed muscle.

For

For the Cubit, although throughout his length all the muscles are compassed with a strong membrane which fasteneth them together, holdeth them in their places, and like a transverse ligament as it were bridleth them vp growing to them very strongly and closely as the proper membrane of a muscle doth; yet there are other ligaments which ioyne the bones together. Wherefore the cubit, which is compounded of the Ell and the Wand, hath ligaments whereby it is fastened to the arme, to the wrist, and also the two bones of the cubit together. To the arme it is fastened with common ligaments, strong but membranous, which tye the Ell to the arme & the wand to the vpper protuberation of the arme. But to the wrist it is articulated with a membranous ligament common to other ioynts, and beside with two proper round ligaments, one fastened to the Ell which runneth from the proesse called Styloides vnto the fourth bone of the wrist and is more gristly then the rest; the second fasteneth the wand to the wrist, for it issueth out of the top or pitch of the wand and runneth into the wrist.

Againe, these two bones of the Ell and the Wand are vaited by a common ligament aboue and below, as also by a peculiar which is membranous and strong running throughout the whole length of both bones, for his situation is in the distance betwixt them, arising from an acute line of the Ell, and inserted into a line of the Wand. It hath also oblique fibres which creepe downward obliquely from the Wand vnto the Ell.

The vse of this ligament is to conioyne and fasten these bones together, to distinguish the exterior muscles from the interior, as also to afford an originall to some muscles, or, at least to adde strength to their originals.

The ligament of the Cubit.

The ligament of the wrist.

Their vse.

CHAP. X.

Of the Ligaments of the Wrist, After-wrist, and the fingers.

THE bones of the Wrist haue common Ligaments with which they are in a manner inuested, for somtimes and in some places they get betwene the bones and become gristly. This common ligament issueth from the lower appendix of the Ell and the Wand. It is very strong and so fasteneth the bones that they become fit for their proper motions which are indeed but obscure, for they are implanted into the appendix of the bone of the After-wrist.

The bones also of the After-wrist are fastned together by common ligaments, which doe not onely compasse the bones orbicularly, but also, neare their extremities in the middle where the bones doe meete one with another they insinuate themselves, becomming of the nature of a gristle, so as they passe againe outward and ioyne the bones of the After-wrist to the wrist.

Finally, the knots or knuckles of the fingers are fastened together with common Ligaments, besides which there are yet in the hand other ligaments which do not serue to articulate or ioyne the bones, but do onely incompasse and containe the tendons that go vnto the fingers, least when they are moued they should slippe out of their places. This kind of ligament is double, one at the inside of the wrist like a bracelet on the inside especially, and holdeth together all the tendons that fall downe to the hand: from it also somtimes proceedeth the tendon of the muscle called *Palmaris*.

The other ligament is on the outside where the wrist is articulated to the Cubit. It taketh his originall from the two forenamed appendices or out-shootes, and is spread over the whole breadth of the Cubit. At the first sight it seemeth to be but one, but when it is dissected it appeareth to be six transverse ligaments, which like Rings are shot ouer the tendons of the muscles that extend the fingers, whereby those tendons are contained or fastened together.

The first proceedeth out of the Ell into the Wand and runneth vnto the Sinus or cavity which is common to them both and is peculiar to the sixt muscle that extendeth the fingers.

The second belongeth properly to the Ell and to the first extending muscle of the wrist.

The third is proper to the Wand and to the extending muscles of the forefinger, the middle finger and the Ring-finger.

The fourth is an exceeding narrow Ring belonging to the slender tendon of the muscle that leadeh the fore and middle fingers from the thumbe.

The fift maketh a way for the second extender of the wrist, and for that muscle which turneth the thumbe toward the forefinger; sometime also a peculiar ligament couereth the tendon of the Thumbe.

Finally,

The ligaments of the wrist.

Of the after-wrist.

Of the fingers.

6 transverse.

Other liga-
ments of the
fingers,

Finally, the fixt transmitteth the three tendons of the second muscle that extendeth the Thumbe.

Moreover, every finger hath ligaments which run throughout their length, arising from the sides of their inner bones which are long and like canals; these do containe or keepe the tendons that bend the fingers in their cavities, least in the flexion they should strut vp out of their place or goe astray.

To conclude, there are other membranous Ligaments, or rather mucous membranes, but redder then the other membranes of the Tendons, which after the manner of Ligaments couer the Tendons that are transmitted to the hand and the fingers, involuing them for their more security, from which sometimes the muscles take their originall, and so much of the Ligaments of the Hand.

CHAP. XI.

Of the Ligaments of the Holy-bone, the Hanches, and the whole Legge and Foote.

IT remaineth now that we proceed vnto the Ligaments which tye the Hanch-bones and bones of the Coxendix and Holy-bone, as also those that fasten the share-bones and which belong vnto the legge.

The lig. of
the hanch.

The ligament which tyeth the hanch bone to the holy bone is a common ligament, broad, membranous and strong, yea in that part where it goeth betwixt the bones it seemeth both in strength and thickenesse to be gristly, the better to constringe and fasten that loose coniunction. Hence it is saith *Bauhine*, that in the travell of a woman, if the impression or throae be more violent, the connexion will yeeld somewhat.

Of the Holy-
bone.

That which tyeth the holy-bone to the Coxendix is double, one ariseth out of the coniunction of the fift and sixt holy bones, and is infixed into the acute proceffe of the Coxendix; the other ariseth indeed out of the same place, but is inserted into the posterior part or appendix to fasten the bones the stronger together. Anatomists also do conceiue that this ligament was ordained to sustaine the right gut with his Muscles vnder which there is no bone.

The share-
bones.

The share-bones although they be fastened together by the interposition of a gristle, yet haue they a double Ligament, one which compasseth them about circularly, least in the travell of the birth, or other great and strong motions of the thigh they should be broken, which might well haue hapned if there had bene nothing but bones to hold them. The other ligament is that which occupieth the perforation, membranous it is and consisteth of fibres that run obliquely downward, for because it was fit that the share-bones should be light, a great part of it is (as it were) turned out; and a ligament substituted as well to sustaine the Muscles that belong to the bone, as to distinguish the two *Obturator*s or the ninth and tenth muscles of the thigh.

Of the leg.

The ligaments of the legge are threefold. Some are referred to the articulation of the thigh, others to the articulation of the legge, and others to the articulation of the foot. The thigh is fastned to the ioynt of the Coxendix by a double Ligament, one common and membranous which circlet the ioynt, and this the Grecians call *ισχιον*, by the name of the whole ioynt, because it is much thicker, harder and stronger then other Ligaments that passe the ioynts; which strength was well provided by nature, for the motions thereof are very strong, and besides it sustaineth the whole body. This Ligament lieth vpon the ioynt and the necke of the thigh, but groweth onely orbicularly to the roote of the great proces that the motions of the head of the thigh might not be hindred. The other ligament of the Thigh is round, and because of his hardnesse may be called a gristly nerue. It is seated in the cup of the Coxendix, and ariseth out of the depth thereof where the cavity is lined ouer with fat to make the head mooue more glib, and where the brow or brim of the cup ceaseth: and is inserted into the middest of the head of the thigh on the top thereof, that it might not easily fall out of the socket; for the thigh is heavy, and hangeth, as it were downe from the Coxendix, wherefore when this ligament is laxed and becommeth longer, luxation oftentimes ensueth, yea sometimes it is broken, and although the bone be restored, yet the patient is alwaies lame after, because the two bones do not adhere so close as they did before.

Of the thigh
two.

The first.

The second.

Next

Next follow the Ligaments of the Legge and the Brace. The first Ligament of the leg is membranous and common, which compasseth the whole knee, except that part which the whirle-bone together with the tendons containing it doth occupy, for that is sufficiently constringed and contained by them.

The ligaments of the Legge.

The other is seated in the backside or in the inside of the knee; strong it is and neruous and groweth out of the proceffe of the legge, and being forked or tined, is fastned vnto the lower head of the thigh on either side. The third is exceeding strong and gristly, growing out of the prominent part of the legge betwixt the cauities thereof, and is inserted into a middle canale or bosome betwixt the two heads of the thigh on the backside. The fourth is slender and mucous in the middest of the ioynt of the knee, and runneth vp from the leg into the thigh, but is not to be found in all bodies. The fift is thicke and almost round, couering the outside of the knee, and it fastneth together the bones of the thigh, the Brace, and the Legge. The sixt is yet smaller then the fift and softer, and is fastened to the inside from whence it ariseth, running obliquely vnto the foreside of the leg.

The Legge also is fastned to the Brace, first by a common Ligament in the vpper part neere the ioynt of the knee which embraceth the connexion of the bone on the outside. Againe in the lower part they are ioyned with a common membranous ligament which proceedeth from the legge vnto the Brace which it tyeth thereto.

Moreouer, betwixt the bones of the legge and the Brace; the space is occupied or taken vp by a Membranous peculiar Ligament which groweth throughout the length of the Brace very fast vnto it. Notwithstanding his originall seemeth to be, by the course of his descending oblique fibres, from the leg-bone, and his insertion into the Brace. By the Ligament not onely the bones are conioyned, but also the muscles which occupye the leg are distinguished the forward from the backward, and it also affordeth a strength vnto the originall of these Muscles that grow vnto it.

The Ligaments of the foote are very many, whereof some do containe the tendons transmitted into the foote and the toes, and they are three transuerse, others fasten together the bones of the foote. The first is situated before at the ioynt of the foote with the legge, which fastneth the bones together and transmitteth some Tendons of the Muscles. The second ariseth from the bone of the legge or from the inward ankle, and is inserted into the bone of the heele, and this Ligament maketh three rings, as it were three Ligaments, because there are three cauities for the tendons of the bending muscle of the great toe & of the great bender of the other toes which passe that way. The third ariseth from the outward ankle or from the Brace and is implanted into the heele, it helpeth the Coniunction of the bones, and couereth two cauities to transmit vnder it the Tendons of the two Muscles called *Peronai*, as we haue shewed before in the History of the muscles. The vse of these Ligaments (as is it in the wrest) is, first of all to add strength to containe the tendons of the muscles of the foote that they be not moued out of their places; from these Ligaments also those tendons do receiue a portion, by helpe whereof they are produced or lengthned together with the small strings of the Nerues. In like manner in the lower side of the toes we finde transuerse Ligaments such as are in the Hand, that containe and establissh in their office the tendons of the muscles which bend the second and third ioynts of the fingers. These Ligaments do fasten the bones of the foot, and are referred to the instep, to the wrest, the afterwrest of the foote, and to the Toes. *Platerius* addeth those, a broad Membrane coupling together many Muscles in the Leg, and the Ligament in the soale of the foote, which serueth instead of a tendon.

Of the Foot,

Their vses,

There are also Ligaments which binde the *Talus* or pastorne-bone (for so it is called in Beasts, we call it commonly the Cockall) either to the legge or to the bones of the foote; the first of those that binde the *Talus* vnto the bones of the Legge is common and Membranous and compasseth their articulation, the rest are all gristly. The second ariseth from the inside of the *Talus* where it is receiued by the inner ankle, and is inserted into the Legge bone where it regardeth the *Talus*. The third ariseth from the outside of the *Talus*, and is fastned into the Brace-bone that regardeth the same.

Of the Talus.

The Ligaments that fasten the *Talus* to the bones of the foote are five, the first is common and membranous and compasseth the iuncture of the *Talus* with the heele; and this *Vesalius* maketh the fift. The second is stronger and gristly and ariseth from the lower part of the *Talus* neere his neck, and is inserted into the heele betwixt the two commissures therof with the *Talus*. This Ligaments *Vesalius* accounteth for the third.

The

The third Ligament (*Vesalius* calleth it the fourth) is gristly likewise, and compasseth the whole ioynt on the outside. It ariseth out of the necke of the *talus*, and is fastned to the bone which is like a Boat. The fourth is strong, arising from the necke of the *talus*, and is implanted into that bone which we call the *Dy* or the *Cube*. The fift is strong and gristly, ioyneeth the bone of the Heele vnto the *Cube*, and encompasseth the ioynt round about.

The Wrist.

The bones of the wrist of the foot, are coupled with very hard and gristly Ligaments, either among themselves, or to the bones that border vpon them. To the neighbour-bones, as on the backside the *Cube* or *Dy-bone*, to the necke of the *talus*, and the same vnto the Heele, so three bones are fastned to the Boat-bone, and on the foreside to the bones of the After-wrist. They are ioyned one to another, as in the vpper part or backe of the foot. In like manner in the lower part there is a very strong and peculiar Ligament, which fastneth them on the outside, and tyeth also the hindparts of the bones together, because it insinuateth it selfe among them.

The After-wrist.

Finally, the Ligaments of the After-wrist and the Toes which ioyne them together, are answerable to the Ligaments of the hand, both in their passage and conformation: those also which run in the distances betweene the bones of the wrist are gristly, the rest are membranous. *Archangelus* addeth, that there are common Ligaments which bind and fasten the particular ioynts of the toes, as it is in the ioynts of the fingers. And thus much concerning Ligaments.

The third part, of Membranes.

CHAP. XII.

What a Membrane is, their Uses, and Differences.

Definition of
a membrane.

of the seed, and therefore broad, thin and fast, the organ of the sense of touching, keeping, knitting and separating the partes vnder it.

By the common consent of *Hippocrates*, *Galen*, and almost all Physicians, *μεμβρανή*, a Membrane and a Coat doe signifie one and the same thing. I know there is sometimes some nice difference amongst the *Grecians*, but it is of no great consequence, and therefore I would haue you to vnderstand me to meane the same thing, when I speake of a Coat, and of a Membrane. The definition of a Membrane is much more necessary, which *Laurentius* hath on this manner: *It is a similar part, cold and dry, engendred of the slimy part*

That it is similar it is manifest, because it is vniforme, and though it be wouen with fibres, yet are they not conspicuous. I speake here of true Membranes not of membranous bodies, such as are the wombe, the bladder, the stomacke, the guts, and such like, which make a part in themselves, and wherein all the three sorts of fibres doe appeare. That it is cold and dry, *Galen* teacheth in his booke *De temperamentis*, but yet it is lesse cold and dry then a Tendon, a Ligament, a Gristle, or a Bone: but more cold and dry then Arteries, Veines and Sinewes. The matter of Membranes is the slimy part of the seed, which by the power of heat is stretched or distended; whence it is that a Membrane may easily bee dilated or compressed without danger: onely the Membrane, saith *Galen*, may be safely distended and contracted, and therefore all parts which were to be distended and contracted, are made membranous. A membrane is broad and extensible to inuest and preserue the part: thight and fast for strength, and beside that it may not so easily receiue an influxion of humours, yet thin, lest the weight of it should be offensive. Notwithstanding though it be thin and appeare simple, yet euery Membrane is double; through which duplicature there run veines for nourishment, arteries to conuey life, and nerues to conuey sense, which vessels being slender and fine, it was fit they should be conueyed betwixt two coats.

The organ of
Touching.

The common office of a Membrane is to be the organ of the sense of Touching, as the eye is the organ of Seeing, and therefore the sense of a Membrane is most exquisite. A Nerue is indeed the conueyer of the spirits and carrieth downe the Commandements of the soule; but as in a muscle it is not the primary organ of motion, as in the eye it receiueh not visible objects, so it doth not receiue the first tactiue qualities, onely the Membrane

brane is it which we must esteeme the organ of Touching; and if you despoile the parts of their membranes, you make them also insensible. Hence it is that the flesh of the lungs, of the liver, of the spleene, and of the rest of the bowels is insensible. As therefore the sense of Touching is diffused throughout the whole body of the creature because it is euery where necessary: so likewise are there membranes sprinkled through the whole body almost internally and externally. On the outside the body is inuested with the skin and the fleshy membrane. On the inside the peculiar membranes are almost infinite.

If it be objected out of *Galen in arte medicinali*, that membranes haue onely inbred nor influent faculties such as is sense. We answere with the Reconciler; that *Galen* then speaketh of membranous and broad ligaments which issue from the bones.

Objection.
Galen ex-
pounded.

The three last particles of the definition do elegantly expresse the three principall vses of membranes. They inuest the parts vnder them like a couering, whence they haue the name of coates. They conserue the fibres to make the flesh more firme and stable, they containe the substance of the parts and enclose it round about least it should dissolue and separate part from part.

Moreover, they fasten one part to another, from whence proceedeth the admirable sympathy or society of the parts. So by the *periostia* the bones are al continued one to another; by their common membrane all the muscles are vnited: by the skin the whole body hath his connexion though it be diuers in respect of the structure of parts which are of diuers kinds. Finally, by the helpe of membranes parts are separated from parts, as we may perceiue in our sections of muscles.

The vses of
membranes.

There are other peculiar vses of membranes, to sustaine parts as appeareth in the *Mediastinum*: to hinder the refluxence of humor as the values that are in the heart, in the great veins and such like places, and to leade along and establish the vessels that are to be distributed into other parts, as into the mesentery, the kell, and the fleshy membrane.

The differences of membranes are manifold and are taken from their substance, magnitude, site, figure, conformation or texture, and from the nature of the parts which they inuest or containe. If you regard the substance which is the Mansion-house and Ancient seate of the determinate and particular faculty, then we say that membranes are either lawfull and true or illegitimate. Those are true membranes, to which the definition before giuen will agree, such are the membranes or Meninges of the braine, the *Peritoneum*, the *Pleura*, the *Periostium* and such like; Illegitimate membranes may more truly be called membranous bodies. Of these there are three kinds, some arise from the bones, are broad and insensible, and fasten the ioynts together. Such are called Ligamentall membranes or membranous ligaments. Others are made of the tendons of muscles dilated and so become more like a membrane then a tendon, such are the thin ends of the oblique and transuerse muscles of the *Abdomen*, also the tendon of the muscle that leadeh the leg backward, which they commonly call *fascia latam* the broad swath. To the third kind I referre those membranous bodies which make parts by themselves, which although they be inuested with coates, yet are altogether made of membranous bodies. Such are the bladders of vrine and gall, the stomach, the guts, and the wombe.

The differen-
ces of mem-
branes.
The first:

Againe, those membranes which I called legitimate, are either of a thin or slender substance like vnto broad cob-webbes, such as appeareth in that membrane or coate of the eye that compasseth the Cristaline humour called *Arachnoides* or the cob-webbe coate; likewise in the *Pia mater* of the braine, and in the coates of the Lungs and the Liver; or they are thicke as the *Dura mater* and the membrane of the bladder; or they are fleshy as in the face, or altogether neruous.

From the magnitude some membranes are broad and some are long. The figure of membranes is manifolde according to the variety of the parts which they doe inuest. From the situation some are internall some are externall, some supernall, some infernall. From the context or conformation some haue fibres of all three kinds, some of two kinds, some of one kind onely: others are without fibres and may be torne euery way as paper may.

The second,
&c.

And so much of membranes in generall, of their Nature, vses, and differences. Now wee come vnto their history, and therein we will be but brieue, because we haue intreated of them almost all particularly in their proper places.

M m m m

CHAP.

CHAP. XIII.

A briefe enumeration of all the Membranes.

He number of Membranes is almost infinite, and we haue handled many of them before as they fell in our way in the order of Dissection, now we will gather them into a briefe sum.

The Mem-
branes of the
Embryo.

The Membranes thereof do some belong to the *Embryo* or infant before it be borne, others to the creature after it is borne also. The Membranes that inuolue the infant are three, called *Chorion*, *Amnios* and *Allantoides*: the *Chorion* is so called, either because it containeth the infant, or because it compasseth it like a circle or a crowne; it cleaueth wholly to the wombe by the interposition of the vmbilicall veines and arteries. *Amnios* or the *Lamb-skin* is the receptacle of the sweate. *Allantoides*, so called because it is like a Haggas-pudding is onely found in brute beastes, and couereth the creature not all ouer, but like a broad swath from the end of the brest-bone vnto the hips. Of these we haue spoken more at large in the 5 chap. of the 5 booke, and in the xvi. question of the Controuersies thereto belonging.

Of the Regi-
ons.

The Membranes belonging to the creature after it is brought forth, are vniuersall or particular. The vniuersall we call those which either do inuest the whole body, as the skin and the fleshy membrane: or all the parts of the same kind as the muscles and the bones. The Muscles are all couered with a Membrane which is common to the muscles, thin, nervous and fibrous, which some thinke, doth arise from the *periostium*: but *Bauhine* esteemeth it to take his originall from the sinewy fibres of the Muscles themselves; and it is fastned to them with thin and slender filaments. The vse of this membrane is to inuest and circumscribe the muscles, to separate them from the other parts and to giue vnto them the sense of Touching. The bones are all cloathed ouer from the crowne of the head to the soale of the foote with a membrane which they call *Periostium*, nervous, thin and very strong, yet we may except the teeth, the inside of the scull, and the ioynts of the Bones: of it we haue spoken in the third chapter of the seuenth booke.

The particular Membranes are such as doe inuest a particular region of the body, or one onely part. The Regions are three, the vpper, the middle, and the lower. The vpper Region is on the outside couered with the *Pericranium*, which is seated betwixt the fleshy membrane and the *Periostium*, arising as some say from the processes of the *dura meninx*, as others from Ligaments which passe through the futures of the scull, which Ligaments are stretched ouer that part of the scull against which they issue forth, and so meeting together are vnited into a common Membrane. Of this also we haue particularly entreated in the place last before named.

The Braine it selfe is couered with two membranes called *Dura* and *pia Mater*: of which we haue spoken in the 7 chap. of the 7 booke, and thither referre the Reader for satisfaction, only heere we remember that they compasse not the Braine only, but his Vicar and substitute the spinall marow, yea all the nerues throughout their generations.

The Middle Region is inuested round with a membrane which is stretched vpon the ribs, excepting the twelfth, and is called *Pleura*: of it we haue spoken in the 6 chap. of the 6 booke, as also of the purse of the heart and the *Mediastinum* which arise therfrom, in the seuenth and eight chapters.

In the Lower Belly, the *Peritonaeum* comprehendeth or embraceth all the contained parts, and of it we haue spoken at large in the 10 chap. of the second booke.

Of the parti-
cular parts.

The particular partes of the body are almost euery one couered with their peculiar membranes or coats. The eyes haue fixe, called *Coniunctina*, *Cornea*, *Vnea*, *Aranea*, *Ciliaris* and *Reticularis*, of which we haue spoken in the sixt, seuenth, and eight chapters of the 8 Booke. The tongue is inuested and iudgeth of Sapers by a proper coate arising from the third and fourth coniugations of sinewes. The Gullet, the Mouth, and Palat and the Chops are couered with the same coate that couereth the Stomacke; the Heart it selfe, the Lungs, the Liuer, the Guts, the womb, the bladder and all the vessels haue their particular coats: so haue also the Kidnies and that thicke, which they call *Fasciam* or the swath-band. The Kell is made of the *Peritonaeum* duplicated, so is also the Mesentery. A world of other Membranes there are, which we haue remembred in their particular places, and therefore list not now to trouble either our selues or the Reader with them, seeing they may easily be found by the title of the Chapter in those places to which they belong; we proceed vnto the Fibres, wherein also we will be very short, for we hasten to an end,

CHAP.

The fourth part, of the Fibres or Villi.

CHAP. XIII.

The nature of Fibres.

Fibres are called in Greeke *ῥῆς*, in Latine *Villi*, although that name is sometimes communicated both to Nerves and to Tendons: some call them *κνησίδες*, because they are like the strings or lines in plants, or graines in the wood. *Laurentius* defineth them to bee *Similar parts, cold and dry, ingendred of the Seed, and therefore white, solid and long, like fine spun threads, destinated or appointed for motion, and to hold the flesh of the parts, wherein they are, together.*

The definition
of a Fibre.

The first particles of the definition are so manifest as they need no explication, the latter which designe their use or finall cause wee will open in a few words.

There are two especiall uses of Fibres, Motion, and Preseruatiō of flesh. Motion according to the Physitians, is three-fold, animall, vitall, and naturall.

Their 2 uses.
Motion three-
fold.

Animall or voluntary motion is performed by the helpe of the muscles: a muscle is moved when his fibres are either intended or drawne toward their originall, and therefore, saith *Galen* in the 8 de *Anatom. administrat.* if you cut all the fibres ouerthwart, the muscles will presently loose all their motion.

The vitall motion belongeth to the heart, and to the Arteries, for the heart hath his fibres manifold and very strong, by whose helpe it is distended, contracted, and quieteth himselfe. The arteries also haue their fibres, in their inner coat many transuerse, in the vter coate oblique and right.

That motion we called Naturall, is most manifest in Attraction, Retention and Expulsion. Wherefore all manner of motions proceed from fibres, but their common Action is Contraction.

Notwithstanding, we must know that these naturall Organs had not their fibres allowed them for a peculiar Traction, Retention and Expulsion, but for a common and officiall. So the Stomacke, the Guts, the Veines, the Arteries, the Wombe, the Bladder, the Heart, and such like, did not stand in need of fibres for their priuate nourishment (for the Bones and the Braine, and the Gristles, and the Flesh of the Bowels doe draw their proper Aliment without fibres) but for a common and officiall action. The Heart for the generation of vitall spirits; the Arteries for the commoderation or tempering of the natieue heat; the Veines for the transmission or transportation of Blood; the Stomacke for the making of the *Chylus*; the Guts for the distribution of the same *Chylus*, and the excretion or euacuation of excrements; the Bladder for miction or making of water; the Wombe for Conception, and for the Birth.

Fibres necessary
for officiall
actions.

The other use of the Fibres is the custody or preseruatiō of the Flesh, as well musculous, as that which maketh the proper substance of the part, for the fibres are, as it were, the first *stamina*, or the warpe, whose empty distances, the flesh like the woofe filleth vp. There are also other peculiar uses of Fibres in the Veines and Arteries, to wit, that thereby they might be better extended after all the violent motions of the Blood, and so become lesse subiect to mischiefe.

The second
use.

CHAP. XV.

Of the differences of Fibres.

The differences of Fibres are to be taken from their site, hardnesse, sense, texture, and from the variety of the Organs. From the site they are called Right, Transuerse and Oblique, for if they run lengthwise, then they are called Right fibres. If they run according to the breadth and intersect, or cut the right, then are they called Transuerse or round and circular fibres. If they haue a middle situation and intersect both the right and the transuerse at vnequall angles, then are they called Oblique fibres. The office of the right fibres is to draw, the office of

The difference
of Fibres.

How Retenti-
on is made.

the transuerse to expell, and that of the oblique to retaine. If the right fibres worke alone then the length of the part is shortned, and attraction made; if onely the transuerse be contracted, then the latitude or breadth is diminished, and expulsion made; but if all the fibres together, the right, the oblique, and the transuerse be intended, then the whole part is contracted and retention made, which also they call *Amplexation*. Retention therefore is made not when any one kinde of fibre doth worke, but when all are in action together; for so when we would firmly retaine any thing in our hands we compasse it about on euery side: yet the oblique fibres are said peculiarly to retaine, because when they are contracted, they doe not onely imbrace, for they compasse the part on euery side, constringing and closing together the particles thereof: but the right and the transuerse fibres when they are contracted, doe not onely serue for retention, but these for expulsion, and those for traction.

The second
difference.

The second difference of fibres may be taken from the hardnesse, for some are hard and strong as those of the heart; for the feruent force of the inbred heat did require so much, as also the perpetuall agitation of his necessary motion, others are softer as the fibres of muscles.

The third

The third difference is taken from their sense. Of fibres some are sensible as those which arise from Nerves: Others insensible, as those that proceed from the ligaments of bones. If you regard the texture of fibres, some are so permixed, that they make a continuall body, so true membranes haue their fibres, yea, they are nothing else but fibres conioyned one within another. Others are separated from the substance of the part and haue another vse beside the vse of the part, and these are either simple, as in the muscles (for all the muscles excepting a very few, haue but one kinde of fibres, either right or transuerse, or oblique) or manifold, and so wouen together, that no Art is able to make separation betweene them.

The fourth.

How the fi-
bres are pla-
ced in the
Naturall or-
gans.

So the flesh of the heart is wouen with all three kindes of fibres, and in the naturall organs which serue for naturall motion, if the part haue one proper coat, as a veine, the wombe, the two bladders, then in that coat are all the fibres placed; but if it haue two coats, one externall, the other internall, then are the transuerse fibres placed in the externall coat, and the right and the oblique in the internall. From this generall rule you must except the guts and the arteries, because the guts doe serue for distribution and excretion, and the arteries for the expurgation of the heart. Now Nature is more carefull for the expulsion of that which is hurtfull, then for the traction of that which is profitable.

The last dif-
ference.

The last difference of fibres is taken from the variety of organs, some serue the animal Organs, as the Muscles, the Nerves, the Ligaments, and the Tendons: others serue the Vitall, as the Heart and the Arteries: others the Naturall, as the Gullet, the Stomacke, the Guts, the Bladders, the Wombe, and the Veines. But what euery one of these fibres in their severall courses doe performe, and how they are disposed in the parts, wee haue declared before in the particular History of euery part.

And thus much concerning the fibres: Now we proceed vnto our last taske of the
Bones.

The end of the twelfth Booke.

THE THIRTEENTH BOOKE,
Of the Bones.

The Præface.

Ship that hath been long at sea, discovered many strange Continents and rivers, struggled through many hiddeous tempests, escaped many rocks and quicke-sands; though she hath made no rich returne, yet when she commeth within ken of her owne Countrey, and sees the land lye faire before her: If thou canst imagine (gentle Reader) how sodainly she forgetteth her irksome trauell, thinke also how well apaid I am, that I am come within view of the end of this my tedious Voyage. For I also have trauelled about a *world*, and that for thy behoofe.

In my iourney, if I haue not made many new Discoueries; yet certainly I haue sounded the depths more truly, entered farther into the Continents, coasted the Shores, plyed vp the Frythes, discovered the Inhabitants, their qualities, tempers, regiment of life, their dyet, their apparell, their employments: and in a word, I haue made it easie for thee to reape the profit of many mens Labours, and of mine Owne. Yet thou must vnderstand this but as a Letter of aduertisement from the Coast. I haue not yet brought my Barke about: Many haue shunned *Scylla* and *Charybdis*, and haue miscaried euen in the mouth of the Hauen, where there are more Rockes then in the Maine; Many Reaches, which wee must haue diuers winds to fetch, and therefore thou must haue patience, if wee make not so fresh a Way, but be constrained to winde in by Bourds; and in the meane time, forget not thou to follow vs with thy vowes. For this Shore is buttrest with Rockes on euery hand, the Currants swift, the shallowes many. To breake off our *Metaphor*: The History of the Bones is a busie piece of Worke; their Articulations and Compositions many dissolute and lax, many strict and close; Their Coalitions hard to be discerned, harder to be expressed; Their Perforations, Cavities, Bosomes, Appendancies, Prominences and Proccesses, difficult to distinguish. Now therefore, if at any time, I stand in need of thy patience; (gentle Reader) for my Stile here must be abrupt and broken, hard and harsh of necessity, according to my Argument. If thou canst finde Profit, looke not for Pleasure; and if thou finde it hard to reape in this vnequall Field, remember hee had something to doe that brake vp the Swarth, and sowed it for thee.

C A H P. I.

Of the definition and differences of Bones.

He Bones, saith *Hippocrates*, τὸ σῶμα ἐστὶν ὡς ὁρθότατα καὶ εἰς τὸ παρεχόμενον, that is, doe giue to the whole body stability, rectitude, and forme: for they are, as it were, the carcasse of a ship, whereto the rest of the parts are fastned, whereupon they are sustained, and the whole mounenance of the body is built and consummated. From their figure and magnitude, we esteeme of the figure and magnitude of the rest of the parts: without the knowledge of the Bones we must needs be ignorant of the originals and insertions of muscles, of the courses of the Veines, of the distribution of the Arteries, and of the partitions of the Nerues. The vniuersall *Syntax* or composition of the Bones, from the Head to the Feet, the ancient *Gracians* called σκελετὸν ἀπὸ τῆς σκελεῖν, as it were a dried or arrid carcasse.

The know-
ledge of the
bones necessa-
ry.

Galen's defi-
nition.

Laurentius de-
finition.

The explicati-
ons thereof.

The forme.

The matter.

The efficient.

The end.

Stability.

Rectitude.

Galen defineth the bones to be the hardest, the dryest, and most terrestriall part of the creature. But this definition doth not please the pallats of the new Writers, as being not exquisite or Philosophicall, but made onely for the ruder, and more ignorant sort to innitiate them.

Laurentius defineth them more accurately thus.

A Bone is a similar part, the dryest and coldest of all the rest, made of the earthy crassament and fatnesse of the seed by the formative faculty, assisted by the strength of heat, for the stability, rectitude and figure of the whole body.

And this definition he saith is Essentiall, because it designeth all the causes of Bones, the Efficient, the Materiall, the Formall and the Finall. The forme of similar parts, according to the Physitians, is the Temper, because it is the first Power, whereby and wherewith the forme worketh and suffereth whatsoener the similar part worketh as a similar. Siccity therefore and Frigidity, dryth and coldnesse doe expresse the forme of a Bone. It is dry, because of the exhaustion of moysture and farnesse, made by an intense or high heate. Cold it is, because the heate vanisheth away for defect of moysture. These primary qualities are accompanied with secondary, hardnesse, heauinesse and whitenesse. A Bone is hard not by concretion as yce, for then it would be dissolued by the fire, not by tention as the head of a drumme, but by siccity, as wood.

Heavy it is, because it is earthy, as also because the ayre and the water in it are extreamly densated and thickned: and it is white, because it is spermaticall.

The matter of the Bones is the crassament of the seed, that is, the thicker and more earthy part. *Aristotle* calls it *Seminale excrementum*, the excrement of the seed. For though the seed seeme to be *Homogeny*, yet it hath some parts thicker then others.

There is in it also something fat and something glutinous or slimy. Of the glutinous part, because it may best be extended or stretched, are made the nerues, membranes and the ligaments. Of the fatty part are made the Bones, and this *Hippocrates* confirmeth, when he saith, *where there is more fat then glew or slime, there the Bones are formed.*

The Efficient cause of a Bone is the formative power which some call the Idoll or the Idea of him that ingendreth: this faculty vseth the heat for his Architect, and the spirit for his chiefe workeman, and to these the Philosopher attributeth Ordination, Secretion, Concretion, Densation and Rarification. The heat therefore drinketh vp and dryeth the fatnesse, whence comes hardnesse and solidity. So saith *Hippocrates*, *Bones are condensated by heat, and so grow hard and dry.*

Furthermore this heat, although it be moderate (for the substance of our native heat is well tempred) yet because it maketh a longer stay in a more dense and fast matter, it bringeth forth the same effects that an intense or high heat doth: yea it seemeth to burne, whereupon *Hippocrates* doubted not to say, *that the generation of Bones was made by exsuffion, that is, by burning.*

The finall cause of Bones which *Galen* is wont to call their vse, is well expressed in the last particle of the definition. For the primary and most common vse of Bones is to giue the body stability, rectitude, and figure. Stability, because they are as it were propugnacles or defences against all violence, beside they sustaine the body as the bases or finials of a house sustaine the rooffe. Rectitude, because without bones the creature cannot stand vp-right, but would creepe vpon the ground, as a Serpent or a Worme. *Hippocrates secundo Epide-*

Epidemion, maketh mention of a childe borne without bones, yet were the principall parts of his Body separated and fashioned, but he was not aboue foure fingers long, and dyed soone after he was borne.

Finally, the bones do giue the figure to the body, because from them dependeth the procerity or stature and the limitation of the groweth. For those that haue a great head haue large braines, those that are narrow chested, their Lungs also and bowels are but short and narrow: those that haue small iawes haue also small muscles. By reason of this finall cause (which being it selfe immouable, moueth all the rest) the bones are of that substance which we see, hard, solid, and insensible: hard and solid for so it behooued a pillar or proptor be; insensible *ad sensum*, that they should not be so apprehensie of paine, for because they sustain the burthen of the body and are continually moued, they could not haue endured so diuers motions without paine if they had bene sensible thereof, and then the life of the creature should haue bene alwaies sad and querulous. But this want of sense comes not from their earthly substance; for then the teeth which are the hardest of all bones should haue no sense; but because there are no nerues diffeminated through their substance.

Why bones are insensible.

The differences of Bones are to be taken saith *Galen*, as also the differences of singular parts from those things which follow the essence or happen thereto.

The differences of bones.

The essence of a bone, that is, his cold and dry temper doe the Tactile qualities follow, Hardnesse, Softnesse, Density, and Rarity; the accidents are Magnitude, Figure, Situation, Motion, Sense, and the like.

The first diuision therefore of bones is, from their hardnesse. Some bones are very hard as those that are called Stony bones and the Teeth; others soft in respect, as the spongy bones and those which we call *Appendices* or *Appendants*; others are simply hard as all the rest.

From the hardnesse.

From the magnitude some bones are great, some little, and some moderate. There are among the Anatomists that account those bones to be great which are of a large bore or very hollow and medullous or marrowy. But we make account of such bones for great as are great in quantity, whether their marrow be lesse or more, for the hanch-bones and the shoulder-blades which are not hollow nor medullous are yet great bones, But because the quantity belongeth to Dimentions and Dimention is three-fold, long, broad, and deepe, therefore from the magnitude of bones may be taken a three-fold diuision of them. For some are long as the thigh bone, others are short as the bones of the fingers: some are broad as the shoulder-blade and hanch-bones: others narrow, some crasse or thicke, others fine or thinne.

Magnitude.

From the figure some bones are plaine, some round, some haue three sides, some haue foure, some are like a boar, some like a Cube or Dye, some like a Mallet, or an anuill, or a stirrop, &c.

Figure.

To the figure also we referre (as the best Physitians doe) the passages and cauities, the smoothnesse or roughnesse. Some therefore are solid, others not solid: some smooth and some rough; I call that solid which is not hollow, Solid bones therefore doe either appeare altogether solid hauing no cauities or dens in them, or at least none sensible, as the bones of the eares and the nose; or else they appeare solid on the outside, but within are full of perforations and holes like sponges, as are the bodies of the rackbones. To solid bones wee oppose those that are hollow, that is, such as haue a sensible or conspicuous canity, which *Galen* calleth *κοιλια*, a belly.

In these is that substance contained which we properly call marrow, in latine *Medulla*, and therefore such bones we say are medullous, that is, marrowy bones.

From the situation there may a twofold difference of bones be taken, because vnder the name of situation we comprehend the position and the connexion.

If you respect their position, some are vpper, others are lower, some on the fore-side, others on their hindside, &c.

If their connexion with other parts, some are fastened by muscles, some by ligaments, and some by gristles. From motion, some bones are moued, as those that are articulated by *Diarthrosis*; some are immouable, as those that are fastened by *Synarthrosis*.

Motion.

From Sense, some bones are sensible as the Teeth, all the rest without senses.

Sense.

Finally, we will adde the difference of bones which is taken from the order of generation. For some bones are generated perfect and compleate, as the small bones of the eares

eares

eaues, the ribs, and the cannell or coller bones. The bones of the eaues, because it was fit they should be very hard and very dry the better to resound. The ribs because they were to make the cavity of the chest wherein the heart was to moue from the very birth. The coller bones because they tye the armes to the body and strengthen the brest. Other bones are at the first imperfect a little differing from Gristles, as the bones of the Head and many in the body beside.

And thus much of the differences of bones; now we proceede vnto their parts.

CHAP. II.

The particular parts of bones and an exposition of many appellations or names, of which we shall haue frequent vse in the History of the Bones.

Three parts of a bone.

N Bones two things are to be considered; their parts and their cavities. The parts of a bone are three-fold; the principall part whereof the bone consisteth; the part that groweth to the bone, and the bunching part of the bone. The principall part of the bone hath no proper name belonging thereto, but is called by the name of the whole bone. The part that groweth to the bone is properly called *Epiphysis*. That part which buncheth or beareth out beyond the plaine surface is called *Apophysis*. The principall part is the primary bone made by Nature, as a man should say, at the first hand or according to Natures first intention. This is the basis of the rest and occupieth the middle place as being the hardest part; for it is in the generation of bones as in the structure of the Vniuerse, that which is hard and earthy is placed in the Center.

The principall.

The Appendix.

To this principall part oftentimes groweth another which the *Gracians* call *ἐπιφύσις*, the *Latines* Appendix, we may call it an Additament, or if you will we may retaine the Latine word Appendix, because it is growne in vse amongst vs. For as if Nature had forgotten her selfe & made the bone too short, she eeketh it out by this Appendix as worke-men vse to lay stones or timber vnder their postes or pillars to lengthen them when they are too short. This appendix *Hippocrates* often calleth *μεγμν*, which we note but by the way.

An appendix therefore is a bone by it selfe, fastened to the whole bone by *Symphysis* or *Coalition*; not the vnition it selfe of one bone with another, for so there should be no difference betwixt *Symphysis* and *Epiphysis*, *Coalition* and the *Appendix*. That it is a bone by it selfe is manifest because it hath a proper and peculiar circumscription, and in yong creatures may easily be separated without coction or putrification; yet it hath often been obserued that in young children it hath been luxed, if I may so say, by a blow or by a fall and separated from his bone. This Appendix is fastened to the principall bone by that kinde of *Symphysis* or *Coalition* which is made without a *Meane*, because the extremities or ends of the primary bone are softer then their middle part. Now the substance of an Appendix is rare and lax, but saith *Aristotle*, *Soft things are easily contained in the termination of another, and yeeld vnto them*. This *Coalition* is not made by a plaine superficies or surface but by a mutuall ingresse of a head and a Sinus or bosome, which kind of coniunction doth much resemble that which afterward we shall call *Ginglymos*.

Their Coalition.

Their substance.

The substance of an Appendix is rare and lax, at first gristly, but in proceffe of time it groweth harder and drier because in the motion of the ioynts and their attrition the heat is stirred vp which drieth and hardneth it. To the extremity of the Appendix Nature hath added a gristle that they might not be so subiect to outward iniuries, or if they happen to be broken yet the softnesse of the gristle may helpe them to reuinite againe. In old bodies they are so vnited with the principall part of the bone that they can very hardly be separated, yea they seeme to be very parts of their bones. All bones haue not this Appendix, for in the lower iaw there is none. In some bones there is but one, as in the rootes of the ribs and in childrens teeth: in others it is double one at either end, as in the Legge, the Brace, the arme, the Ell and the Wand. In others it is treble, as in the haunch-bone; some haue foure as the bone of the thigh, three in the vpper part and one in the lower. The *vertebra* or rack bones haue fise, two in the transuerse processe, two in the bodies, and one in the Spine. There are many Appendices which are ordinarily by the people taken for processe, as the tooth of the second Rack-bone, the great Trochanter, Stryloides, &c.

The

The vſes of theſe *Appendices* or Appendances are diuers, *Galen* acknowledgeth a double vſe : one that in Bones which haue marrow they ſhould ſerue in ſteade of a couer to keepe the marrow in, for that which is hollow and ſolid as is the lower iaw, doth keepe in his marrow without an Appendix.

The other vſe is for more firme articulation, for a bone is better eſtabliſhed vpon a large *Baſis* whereas if the bones ſhould determine into a ſharper poynt, their conſtruction or articulation would be more dangerous & deceitful, & the bones eaſily and vpon a light offence would fall out of their ſeates. And herein Art imitateth Nature, for the *Baſis* or foote of a *Finiall* or *columnne* for more ſecurity is made large and broad. But becauſe theſe Appendances are broad, Nature made them rare and lax, leaſt their waight ſhould preſſe too much vpon the parts vnder them.

To theſe vſes of *Galen* we may alſo adde others, firſt that out of them the *Ligaments* might take their originall, which either faſten the bones or make the tendons or chords of muſcles. *Falopius* obſerued that the *Ligaments* were not extended or lengthned beyond the *appendices*, as if the appendix be ſhort the *Ligament* is alſo ſhort.

Moreouer, the Appendix being ſofter then the bone and harder then the *Ligament*, interpoſeth it ſelfe as a mediator betwixt the coniunction of the bones; for ſuch is Natures vſe to couple things that are extreame by thoſe that are in a meane.

Adde hereto, that by the interpoſition of the *Appendices* the fracture of a bone, if it happen, is ſtayed and goeth no further, as appeareth in the ſutures of the head.

Againe, *Appendices* were made for the conſeruation of the ioynt. For a bone being very hard, if one hard thing ſhould haue bene committed or conioyned to another, by reaſon of their continuall motion they would haue bene broken or at leaſt worne as the teeth are, and therefore the bones were conſtrued or conioyned by ſofter bodies.

Some out of *Hippocrates* doe imagine that the Appendix was made to be as it were the belly of the bone wherein his Aliment is concocted, from whence by degrees it is percolated or ſtrayned into his ſpongy or hollow parts. And thus much of the ſecond part of a bone.

The third part of a bone the Grecians call ἀπόφυον, the Latines *Proceſſum*, many other appellations it hath in Greeke and Latine, but we take the moſt common. In Engliſh we call it a *Protuberation* or *Proceſſe*, and may be deſcribed thus : A proceſſe is a legitimate part of the bone, breaking out of the bones it ſelfe, and bunching beyond his plaine and euen ſurface : ſuch as are the knags of Harts-hornes. Euery bone almoſt hath his proceſſes, but they are moſt conſpicuous in the lower iaw and in the racke-bones.

Their vſe we acknowledge to be double : one for the originals and implantations of many parts, eſpecially of muſcles; for vſeſſe the bones had protuberations or productions in them, neither muſcles nor ligaments could grow from them. Another vſe of theſe proceſſes is, that in ſome parts they ſhould ſupply the place of a defence as it is in the racke bones and in the ſhoulder-blades.

The differences of *Appendices* and *Proceſſes* are taken from their Figure. For if the protuberation be round it is called a *Head*, whether it be an appendix or a proceſſe, If from a narrow beinning it be by degrees dilated, it is called a *Necke*. If it end in a coner or an acute termination it is called *κονοειδης*. An Appendix therefore or a Proceſſe is three-fold according to the variety of their figure, a *Head*, a *Necke* and a *Point*.

The *Head* is double, one which is abſolutely called a *Head*, long and large, ſuch as is the head of the Thigh-bone: the other depreſſed which is commonly called *κόνδυλος*, we may properly Engliſh it a *Knuckle*.

The *Necke* is only of one ſort, herein differing from the head, that for the moſt part the head is an appendix and the necke a proceſſe.

That which is called *κονοειδης*, the *Cone* or *Poynt*, an acute or ſharpe proceſſe, is manifold. One is like a *Bodkin*, another like an *Anchor*, another like a *Crowes beake*, and another like the nipple of the *Dugges*.

The firſt is called *Styloides* or *Graphoeides*; the ſecond *Anchyroides*, the third *Coracoeides*; and the fourth *Mastoides*.

Thoſe proceſſes which at the circumference of the cauities doe hang out like lippes and increaſe the depth of the *Cup* are called *Browes* or *Lips* or *Verges* or *Brimmes* or what you liſt, for all theſe things they doe reſemble. And theſe are the parts of a bone in general.

A proceſſe.

Their vſes.

How they differ from appendices.

The head.

The necke.

The poynt.

The

Differences
of cavities.

The second thing to be considered in a Bone was cavity, which was made for the articulation or construction thereof. Of cavities there are two sortes; some are deepe and some are shallow. The deepe cavities which haue high and large browes about them are called *κοτύλη*, a *Cup*, and indeed it is most like the new fashioned siluer bowles which are round and deepe, and the edges hanging ouer their cavities: such are found in the hanch-bone and in the shoulder-blade. The superficially or shallow cavities are called *γλινδα*, from the cavity of the eye when the liddes are shut: and they are so obscure that at the first sight you may doubt whether they admit another bone or themselves enter into another: These cavities whether they be deepe or shallow, *Hippocrates* calleth *βαθυιδες*. And these are the Appellations and names which we thought good in this place particularly to explaine, because in the History of the Bones you shall meete with very frequent mention of them. Now we proceede vnto the structure and connexion of bones.

CHAP. III.

Of the structure and connexion of Bones in Generall.

Why mans
body was not
made of one
bone.

An being created for Vnderstanding and Action, to receiue infinite images of Sensible things, & to flye or apply himselfe to the diuers objects of his appetite, stood in need of locall motion, but if he had been made of one continuall bone, how could he haue bent or extended or compassed his body; how could he haue apprehended any thing or moued himselfe forward to attaine it? No; he must haue stood like a trunke or a blocke, and the creature that was made to command all the rest would haue beene a right Mauchen or gazing stocke to the rest. Nature therefore for the better accomplishment of the varieties of motions, hath wonderfully framed the body of man of a Packe or Set of bones, of diuers kinds and manifold figures. And this diuersity is also of as great consequence *ad vtilitatem*, that when one bone is broken the fracture might stop and not offend the rest. Hereby also is there fit way made for Transpiration of fumid vapors: hereby are the parts discriminated or distinguished one from another: hereby is the ingresse & egress made for the vessels. Notwithstanding though this connexion be diuers, yet is it so strangely fitted together that al seeme to be but one: one I say either by Continuity or by Contiguity at least. The vniuersall compage or coagmentation of the bones is called a *Syntax*, and the packe of bones so fitted together is called a *Skeleton*.

What a Skeleton
is.

The manner of this *Syntax* or cōposition is double, for it is made either by *Articulation* or by *Coalition*. *Articulation* we define to be a naturall structure of the bones, wherein the extremities or ends of two bones do touch one another. So that the whole Nature of *Articulation* consisteth in the Contaction of extremities or ends. This Articulation according to *Galen* is double; one laxe and loose called *Diarthrosis*, for *δια*, in composition of words signifieth a separation or loosenesse; another strict and so compacted that there is no space left for any motion. And this kinde is called *Synarthrosis*. The first is with manifest motion; the second hath no motion at all, or if it haue any it is scarcely conspicuous.

Diarthrosis.
Enarthrosis.
Arthrodia.

Of *Diarthrosis* there are three kinds, *Enarthrosis*, *Arthrodia* and *Ginglymos*; *Enarthrosis* is when the cavity that receiueh is deepe, and the head inserted into it long, and such is the articulation of the Thigh-bone with the Hanch. *Arthrodia* is when the cavity is superficially or shallow, and the head depressed or almost plaine; and such is the articulation of the lower iaw with the Temple-bone and the Nowle-bone with the first spondell. *Ginglymos* is when the same bone receiueh and is receiued, as it is in the hingedes of a doore, wherein the yron that carrieth the hinged and the hinged that is carried doe mutually enter one into another.

Ginglymos.

In *Ginglymos* therefore the gibbous part of one bone entereh into the hollownesse of another; and againe the *Sinus* or bosome of one bone admitteth the gibbous or embowed part of another.

This *Ginglymos* is made two wayes; for either the same bone is receiued by one and receiueh it againe, or it receiueh one bone and is receiued of another.

An example of the first we haue betwixt the Arme and the Cubit: of the second in the Racke-bones of the Backe, for the *vertebra* in the middest receiueh that spondell which is aboue it, and is receiued by that which is vnder it.

Of

Of *Synarthrosis*, there are also three kinds, *Rhaphe*, *Harmonia*, and *Gomphysis*. *Rhaphe* the Latines call *Sutura*, a seame, for it is like the seame of a garment: and it is a double, one toothed like a Saw or a Combe, the other plaine, like the Scales of a Fish, or the Mayles of a Harneffe, or Nailes of the fingers, one thrust vnder another. The first we finde in the sutures of the Scull, the second in the Temple-bones. *Harmonia* is an articulation by a simple line, either right, oblique or circular, and so are almost all the bones of the vpper Iaw ioyned together. *Gomphysis*, is when one bone is fastened into another, as a naile into a boord, and so the teeth are set in the Iawes. And these are the two kinds of articulation, *Diarthrosis* and *Synarthrosis*, vnto which we may adde out of *Galens* twelfth chapter of his booke *De ossibus*, a third which is a neutrall articulation, halting betwixt two, and participating of them both, yet being neither perfectly: and this neutrall articulation, because the motion thereof is obscure, may be said to belong to *Synarthrosis*, but in respect of the manner of his composition which is made by a cavity and a head, it may be called *Diarthrosis*. Such is the articulation of the ribbes, with the breast-bone and the rackes: such also is seene in the wrist and the instep. And these are the differences and kinds of articulation.

The neutrall articulation.

The other kinde of composition is called *Symphysis* or *Coalition*. For Nature well foreseeing that the articulation of great bones was not very secure, because they might easily slip out of their seats, she therefore deuised a more streight or neere kinde of coniunction or colligation, which Anatomists doe call *Symphysis*, wee coalition, which is nothing else but a naturall vnion of bones, by which two bones are continued together and made one, so that the nature of coalition consisteth in continuity, as the nature of articulation did in contiguity or contaction of extremities.

Coalitions

This *Symphysis* or coalition is double, one with a mean, another without a meane. Those bones that are soft and fungous, doe grow together without a *Meane*, so all appendancies almost, because they are soft and gristly, are vnited with bones by coalition, but those that are dry and hard, cannot be vnited without the inter-vening of another body. That middle body is three-fold, a nerue, a gristle and flesh. And hence proceed the three differences of *Coalition*, *Synchondrosis*, *Synneurosis* and *Synsarcosis*. An example of *Synchondrosis* we haue in the share-bones, and in the lower Iaw. An example of *Synneurosis* in euery *Diarthrosis*, but you must vnderstand that by a nerue in this place, we meane a ligament. An example of *Synsarcosis* you haue in the bone *Hyois*, and in the shoulder-blades, but by flesh here, we vnderstand muscles. We haue here added a Table which containeth their pedigree,

whereto we will not so exactly stand, as that there may be no exception taken

thereto by curious Schollers, either in the manner of diuision, or in the

appellations, although I presume such as will be most ready to

finde fault, will not finde it so easie

to amend.

The

The Table of Connexions.

| | | |
|--|---|--|
| | <i>Inarticulation</i> , when the Cup is deepe, and the Head long, and it is called <i>Enarthrosis</i> , as betwixt the Thigh and the Hip. | When the same bone is received by one bone, and againe receiue the same, as betwixt the arme and the cubit. |
| | <i>Adarticulation</i> , when the cup is shallow, and the head oppressed, and it is called <i>Arthrodia</i> , as betwixt the lower iaw and the temple-bones, the Nowle and the first Rack-bone. | |
| | <i>Hinge-bung</i> , when the same bone receiue the same bone, and is received, it is called <i>Ginglymos</i> , and it is made two wayes. | When it receiue one bone, and is received of another, as a middle racke-bone, receiue the vpper and is received of the lower. |
| | <i>Seame called sutura</i> , and it is double. | <i>Toothed</i> like a Saw or a Combe, as the futures of a Scull. |
| | <i>Coarticulation</i> , which is a strict and well compounded iuncture, and it is called <i>Synarthrosis</i> , it is also of three sorts, by | <i>Plaine</i> , like the Scales of a Fish, as the temple-bones with the scull. |
| Bones are ioyned or compounded by | <i>Articulation</i> , whose nature consisteth in contiguity of extremitie, & it is threefold. | So almost are all the bones of the vpper Iaw articulated. |
| | <i>Mortize</i> , which is when one enters into another, as a Tenant into a Mortize, so the teeth are fastned in the Iawes, and this is called <i>Gomphysis</i> . | <i>Right</i> .
<i>Oblique</i> .
<i>Circular</i> . |
| | <i>Galen</i> addes a third, which is neutrall or doubtfull; and is neither the one nor the other, but partaketh of them both, agreeing to <i>Coarticulation</i> , by reason of the obscurity of the motion, and to <i>Dearticulation</i> , if you regard the composition of the heads, and the cavities. Such is the articulation of the ribbes, with the breast bone and the racke-bones, and that of the bones of the wrist and instep. | A Gristle, such <i>Coalition</i> is called <i>Synchondrosis</i> , and it is found betwixt the share-bones.
A Ligament called <i>Symenrosis</i> , and is found in all <i>Dearticulations</i> .
Flesh called <i>Synsarcosis</i> , and is found in the bone <i>Hyois</i> , and the shoulder-blades. |
| <i>Coalition</i> or vnion, whose nature consisteth in continuity, and it is called <i>Symphyis</i> . It is double: | Without a <i>Medium</i> or <i>Meane</i> , so doe soft and fungous bodies grow together, as almost all Appendancies. | |
| | With a <i>Meane</i> , as dry and hard bones which are not vnited without the interposition of some middle body: & that is, | |

when the same bone
is joined by one bone,
and receive the
as betwixt the
and the cubit.

when it receive
one, and is received
her, as a middle
bone, receive
upper and is recei-
the lower.

the shoulder.

To this place also we have thought good to adde six severall Tables containing the Sceleton or packe of Bones throughout the whole body, as they appeare before, behind, and on the side in a man; the Sceleton of a woman; of an Infant new borne, and of two vntimely Births, with their descriptions at large, by which the Reader may be well initiated before he cometo the particular History.

TABVLA I.

TABVLA III.

TABVLA II.

Tab. 1. sheweth the forepart of the Sceleton of a man, that is to say, the whole packe of the Bones and Gristles in a mans body, as they appeare on the fore side.

Tab. 2. sheweth the back side of the Sceleton.

Tab. 3. sheweth the laterall part of the sceleton. Wherefore we will put all these three descriptions into one.

A 3. The Coronall Suture called in Greeke *σφηνοειδής*.

B 2 3. The suture like the letter Δ called *λαμινειδής*.

C 2. The sagittall suture called *ὀβελιαία*.

D 2 3. The scale-like Coniunction cald *λεπιδειδής*.

a, 2, 3. Os verticis, or *synipitis*, the bone of the Syniput, called Os *βρεγματική*.

β, 1, 3. The forehead-bone, that is, *μετωπιαία*.

γ, 2, 3. The bone of the Nowle or *νύς*.

δ, 2, 3. The bones of the temples or *κεφαλαίαι*.

ε, 3. An appendix in the temple-bone like a Bodkin, *στροφαίτης*.

ζ, 1, 2, 3. A proceffe in the temple-bone like the teate of a dugge, called therefore *Mamillaris* and *μαστοειδής*.

η, 2, 3. the wedge-bone, *σφηνειδής*.

θ, 3. the stony part of the Scull.

θ, 3. a proceffe of the wedge-bone much like the wing of a Bar, and therefore called *πτερυγοειδής*.

ι, 1, 2, 3. the yoke-bone *ζυγία*.

κ, 1, 3. the lower iaw.

λ, K, L, M, N, 1, 2, 3. the backe or the spine, *σπονδυλική*.

From I to K, the Necke, *αχλαίτη*.

From K to L, the Rackebones of the Chest.

From L to M, the rackebones of the Loynes.

From M to N, the Holy-bone, *ιερόν*.

N, the Rump-bone, *ὀσφυς*.

O, 1, 3. the brest-bone, *στέρνον*.

P, 1, 3. the Sword-like gristle of the brest, *ξίφοειδής*.

Char. 1, 2, 3. as farre as to 12 in all three Tables, shew the twelve ribs of the Chest cald *πλευράι*.

Q, 1, the clauicles or collar bones, *κλείδες*.

R, 1, 2, 3. the shoulder-blade, *ωμοπλάτης*.

λ, 1, 2, 3. the vpper proceffe of the shoulder-blade, or the top of the shoulder, called *ἀκρώμιον*.

μ, 1, 3. The lower proceffe of the shoulder-blade, called *ἀγχιρροειδής*.

S, 1, 2. the bone of the arme, called *Humerus* and *βραχίον*.

T, V, 1, 2, 3. the Cubit *πῦξ*.

X, 1, 2, 3. the wand or the vpper bone of the Cubit, called *καρπία*.

Y, 1, 2, 3. the ell or the lower bone of the Cubit, called *πῦξ*.

z, 3. the proceffe of the Cubit, *ὠλέκρνον*.

ξ, 1, 3. the proceffe like a bodkin or probe, called *στροφαίτης*.

ZZ, 1, 2, 3. the wrest *καρπός*.

Π, 1, 3. the after-wrest *κεφαλαιόπυον*.

ΔΔΔ, 1, the fingers *δακτύλοι*.

Θ, 1, 2, 3. the bones ioyned to the sides of the Holy bone, on each side one, distinguished as it were into three parts.

ο, 1, 2, 3. the first part called the Haunch-bone, Os *Ilium*, *λαγόν*.

π, 1, 2, 3. the second part the bone of the Coxendix *ισχίον*.

ρ, 1, 2, 3. the third part the share-bone, Os *pubis*, *ἡβης*.

σ, 1, 2, 3. a gristle going betweene the coniunction of the share-bones.

Δ, 1, 2, 3. the thigh, *μυελόν*.

τ, 1, 2, 3. the greater outward proceffe of the thigh called *Rotator*, *τροχαντήρ μέγας*.

υ, 1, 2, 3. his lesser and inner proceffe.

ζ, 1, 2, 3. the whirlebone of the knee, *Patella Rotunda*, *ἐπιμυελίς*.

Η, Σ, 1, 2, 3. the leg, *μυελόν*.

Φ, 1, 2, 3. the inner and greater bone of the legge, *σφυρημιον*.

Ψ, 1, 2, 3. the vtter and smaller bone of the Legge, called the *Bract-bone*, *Fibula*, *περὶν*.

φ, 1, 2, 3. the proceffe of the Leg or the inner ankle called *Malleolus internus*.

X, 1, 2. the proceffe of the brace of the out-ward ankle, both of them are called in greeke, *σφυλόν*.

Ω, 1, 2, 3. the bone called the cockall, *Talus*, *balista*, Os *ἀσφάλαιον*.

α, 2. the Heele *Calx*, *πῆρνα*.

β, 1, 3. the bone called Os *Naviculare*, *ναυειδής*.

cc, 1, 2, 3. the wrest of the foot called *Tarsus*, consisting of foure bones, *ταρσός*.

d, e, f, 1, 2, 3. three inner bones of the wrest of the foot, called by some *χαλκοειδής*.

g, 1, 2, 3. the vtter bone of the wrest of the foote like a Dye, *κυβοειδής*.

bb, 1, 2, 3. the afterwrest of the foot called *Pedum*, by some *μεταταρσοί*.

ii, 1, 2, 3. the toes of the foot.

k, 1, 2, 3. the seed bones of the foot, called *oscula sesamina*, *σποσμοειδής*.

Table

Table 4. sheweth the Sceleton of the bones and gristles of a woman, that it may appeare all her bones are in proportion lesfer then the bones of a man. But in this Table onely those parts are marked with letters wherein a woman differeth from a man in her bones and gristles.

TABVLA IIII.

- A, The sagittall suture descending into the Nose, and diuiding the forehead bone, which is sometimes found in women, very rarely in men, but alwayes in Infants.
 BB, the Chest somewhat depressed before, because of the Paps.
 CC, the collar bones not so much crooked as in men, nor intorted so much vpward.
 D, the breast-bone perforated sometimes with a hole much like the forme of a heart, through which veines doe ranne outward from the mammary veines vnto the Paps.
 E, the gristles of the ribs, which in women are somewhat bony, because of the weight of the Dugs.
 F, a part of the backe reflected, or bent backward about the loynes.
 GG, the compasse of the hanchbones running more outward, for the wombe to rest vpon, when a woman is with child.
 HH, the lower processes of the share-bones, bearing outward that the cavity marked with K, might be the larger.
 I, the anterior commissure or coniunction of the share-bones filled vp with a thicke gristle, that in the birth they might better yeeld somewhat for Natures necessity.
 K, A great and large cavity circumscribed by the bones of the coxendix and the Holy-bone.
 L, The Rump or Coccyx, curued backward to giue way in the time of the birth.
 M, the thigh bones by reason of the largenesse of the foresaid cavity, haue a greater distance betwixt them aboue, whence also it is that womens thighs are thicker then mens.

Table 5. sheweth the Sceleton of a child new borne, wherein its bones are yet either gristly or membranous.

TABVLA V.

- a, A thicke and (for the most part) square membrane betwixt the bones of the forehead and the Synciput which filleth vp the parts betwixt them.
 c, the bone of the forehead diuide d into two equall parts by the sagittall suture.
 d, the separation of the lower Jaw into two bones.
 e, the Scaly part of the Temple bones, which in the middest indeed is bony, but in the circumference membranous.
 f, the other part of the Temple bone which waketh a part of the stony bone, where the hole of hearing is gristly.
 l, the sockets of the lawes made to receiue the teeth.
 mm, the body of the rackbone, distinct from his backpart.
 nn, the backpart of the rackbones, consisting of two broad and small bones, and of gristly processes.
 o, the Holy-bone made of five rackes with a gristle betwixt them.
 p, the Rump gristle.
 q, the breast-bone, gristly in the circumference, but in the middest compounded of many bones.
 rr, the large part of the Coxendix made of three bones, with a gristle betwixt them.
 s, the second part of this bone making the parts of the Coxendix and the share-bones.
 t, the third part behind, making the same parts with the second.
 u, the whirle of the knee which is gristly.
 x, the wrist of the hand which is gristly.
 y, the After-wrist of the foot gristly.
 z, Although all the Appendances of the bones in Infants are gristly, yet this z marketh the most notable, as those of the Arme, the Blade, the Cubis, the Hanch-bone, the thigh and the Leg.

Table 6. sheweth the Bones and Gristles
of an Embryo or untimely Birth.

The first figure sheweth the Embryo at 24
dayes old, already formed and proportioned,
when all the Bones are like to curdled cheese
or to Butter.

Fig. 2. sheweth the tender bones of an A-
bortive fruit, about 3 months old, which are
more gristly then they are in a child borne in
due time.

a 1. Betwixt these letters in that space which on
the top of the Scull is soft and membranous, the
Arabians call it *Zendeck*, and commonly it is
called *Fontanela*.

a 2. a thicke membrane which goeth betweene
the forehead bone and the bones of the *Syn-
ciput*.

b 1. the ends of the Arme gristly.

b 2. membranes betwixt the diuision of the
bones of the head where afterward the futures
are.

c 1. the soft appendances of the Ell and the
Wand almost separated from their bones.

d 1. the appendices of the thigh and the legge.

e 1. the bones of the after-wrest of the foot, al-
together gristly.

a 2. the nayles of the fingers which are conspi-
cuous euen in an abortive Infant.

FIG. I.

CHAP. IIII.

A brieft diuision and enumeration of all the Bones in the Body.

The diuision
of the Sceletos.
The Scull 8.
3 of hearing.

THE whole Set or Pack of Bones called *Sceletos* we deuide into three parts; the
Head, the *Trunke*, and the *Ioyntes*. The Scull which is called *Cranium* or *Calua*,
consisteth of eight bones, sixe proper and two common. The proper bones are the
Fore-head bone, the Nowle-bone, the two bones of the *Syn-
ciput*, and the two
Temple bones, wherein are contained the three small bones of the Eare, the Mallet or Ham-
mer, the Stithy or Anuell, and the Stirrup. The two common bones are the Wedge bone
and the Spongy or Syue bone.

The iawes 13
Teeth 32

The Face contains both the Iawes, the vpper and the lower. The vpper Iaw consisteth of
eleuen bones. The lower Iaw of two onely, vnto both these are 16. Teeth belonging, arti-
culated by way of mortize or by *Gomphosis*, of which foure are called *Incisores* the Shearers,
two are called *Canini* the Dog-teeth, and ten *Molares* or the Grinders.

The spine 28.

The Trunke is deuided into the Spine, the Ribs and the bone without a name. The Spine
hath foure parts: the Necke, the Backe, the Loynes and the Holy-bone. The Necke hath
seuen rackbones, which are called *vertebra*. The Backe twelue, the Loynes siue, and the Holy
bone 4. or 6, whose extremitie is called *Coccyx* or the Rump. The ribs are twelue on either
side, seuen true Ribs and siue bastard Ribs, to which are articulated on the foreside the Brest-
bone, aboue the Coller Bones, and on the backside the shoulder blades. The bone without
a name (and I thinke it better so to leaue it then to giue it an vnfit name) hath three parts;
the Hip, the Hanches and the the Sharebones.

The Rump.
Ribbes 24.
Brestbone 3.
Coller bone 2
Shoulder-
blades.

Arme 1.
Cubit 2.
The hands 54.
The feed-
bones.

The third part of the *Sceletos* is called the Ioynts, and there are two of them, the Hand and
the Foote. The Hand is deuided into the Arme, the Cubit and the Hand properly so called.
The Arme hath one Bone, the Cubit 2, called the Ell and the Wand. The Hand properly so
called is deuided into the Wrist, the Afterwrist and the Fingers. The Wrist hath eight
Bones, the Afterwrist foure, the fingers fifteen, to which you may adde the Seede bones
called *Sesamoidea*.

The thigh 1.
Leg 2.
Feet 52.

The Foote is deuided into the Thigh, the Legge and the Foote properly so called. The
Thigh hath on bone: the Legge two, one retaineth the name of the whole and is called
the Leg-bone *Tibia*, the other we call the Brace-bone, in Latin *Fibula*. The Foote properly
so

so called hath three parts, as had the Hand, the Wrist, the Afterwrist and the Toes. The Wrist which is called *Pedium* hath seven bones: the Afterwrist *Metapedium* five Bones: The Toes foureteene. To all these we may adde the bone of the Tongue called *Hyois* which hath no articulation with any other bone; and this is the brieft summe of all the bones in the body. Now we proceed vnto their particular History.

CHAP. V.

Of the Sutures or Seames of the Scull, and of the substance thereof.

Concerning the Figures or formes of the Head, we haue spoken before sufficiently in the fourth Chapter of the seventh Booke, and therefore here we will not stand either to repeate or enlarge this argument, but come directly to the bones of the Scull.

The Scull therefore is called in Greeke *κεφαλον*, in Latine *Caluaria*, and is that bone which compasseth the whole braine, being put vpon it as a Head-peece or Murrion, for more security and stronger defence, because vnderneath it, are contained so noble and necessary parts.

The Scull also for further security was made round and large, because it was to containe a great quantity of Braine and After-braine. It was not made of one bone for feare least by one wound it might haue been throughout cleft or fractured, but of many ioyned together by sutures or seames, as well for security as also to make the Head lesse subiect to offence: for were it not for these seames, in vehement motions the bones must needs start asunder.

The fashion of these Seames is of two sorts: the one plaine and linear like two boards glewed, or stones cemented together: the other indented like the teeth of two Sawes ioyned together, or like a loose seame of a garment when it is slackly sowed. It is very rare to finde the head without seames, although *Aristotle* report such a thing, as also *Pollux* in his second booke, *Herodotus* in his ninth, and *Columbus* vpon his owne experience. Sometimes we finde the *Coronall* suture to be obliterated, sometimes one of the other, sometimes in old bodies through length of time and drith all the seames do grow together by coalition, as doe the Appendances of bones, and their sutures are so abolished that scarce any footsteps of them do remaine, which in yonger bodies are most conspicuous.

Of all the Sutures saith *Falopius* those of the Temples do continue the longest. *Hippocrates de vulneribus capitis*, and *Galen* out of him doe say, that the sutures do change their position and number according to the different figures of the head, so that in those heads wherein the anterior prominence is wanting therein also is the *Coronall* suture absent; where there is no prominence in the Nowle there is no *Lambdall* suture: yet alwaies the *Sagittall* suture remaineth, and then the figure of the remaining sutures is like T. But where both prominences are wanting, there are 2. lines intersecting themselves through the Scull like X. *Columbus* for this reprehendeth *Galen*, and saith he hath handled sixe hundred thousand Sculls (he meanes a great many in some Church yard or Cloyster) yet neuer found any whose figure was not naturall, or which wanted either the *Coronall* or *Lambdall* sutures. *Falopius* also in this is against *Galen*, and so is *Eustachius*. *Bauhine* cannot approue it, for saith he we often find heads which want either the anterior or posterior prominence and yet haue all the sutures. Againe, some we finde without the *Coronall* sutures, when notwithstanding the fore head beareth out; some without the *Lambdall* suture though the Nowle be bunching: some without the *Sagittal*: some are found without any suture at all, though no prominence be wanting: not that these sutures are deficient from their originall or from the birth, but they are therefore abolished because they oftentimes grow together whether the head be well formed or no. For if the prominences were the cause of the sutures, then where there are no prominences there should be no sutures, but in the side of the head at the Eares where the Scull is depressed there are sutures without prominence.

The Sutures are called *σφαται*, and they are of two sorts; some are proper to the Scull itselfe, some are common to it with the vpper iaw. The proper sutures are againe double, True or False: the True are three, the False sixe. The common sutures are five. The true seames are two transuerse, and one lengthwise, so that together they make such a figure as this.

The first  or the anterior or the transuerse [ta. 7, AB ta. 9, fi. 11. m] is called *σφαταια*, The Coronall suture, because the ancients were wont to weare their crownes in that place; not such Crownes as Kings weare, but such as

Tab. 7. sheweth some bones and sutures of the head. Fig. 6. sheweth the left side. Fig. 7. sheweth the right side, the yoke bones being removed. See the description in Lib. 7.

at this day amongst vs, Gentlewomen doe weare, that is to say, Wyers, or Tyres of Haire, and oftentimes they lay some peece of Scarlet, or such like, vnderneath to defend the mould of the head, (for so wee commonly call it) from the ayer. This future resembleth a transuerse circle, for so it runneth ouerthwart about the forehead as farre as to the scaly agglutinations of the temple bones, and it separateth the forehead bone [ta. 7. L. from I. to K.] from the bones of the *Synciput*, or it ioyneth them together.

The *Lambdoides*.

The second or posterior future [ta. 7. C, D, ta. 9. P. P.] is in the backpart of the head, and ascending obliquely from the basis of the Nowle, to the rootes of the mamillary processes, at each eare determineth at the middest of the sagittall future. This future, because it is like the letter Δ is called *Lambdoides*. It separateth the nowle bone from the Bones of the *Synciput*, [tab. 7. M, from I K.] and the temple Bones. [ta. 7. N.]

But in those men whose Sculls are large behind this future is altered into others of diuers formes; sometimes the Bone is diuided by a transuerse future; sometimes it is circumscribed with a double future, as if a greater triangle should comprehend a lesser; sometimes with a treble, as if a greater triangle should comprehend two lesser; & these bones so circumscribed are by some called *Triangularia*, and are commended as of much auaille in the *Epilepsie* or Falling sicknesse. The third future is in the midst betwixt the former two, [ta. 7. fi. 1. R.] and commonly (as you may see in grown bodies) it runneth from the middle of the *Lambdoides* through the middest of the length of the head to the middest of the crowny future; sometimes it breaketh through it and diuideth the forehead bone, iust in the middest vnto the top of the nose, which is alwaies to be seene in Infants, in some children til they be 7 yeares old, in women but ordinarily, in men more rarely, and especially in those that haue flat faces. It is called *Sagittalis*, because it is straight like an arrow. It diuideth the two Bones of the *Synciput*; sometimes also (as we haue said) the forehead Bone, and sometimes it cutteth also a part of the nowle-Bone: And thus much of the two futures.

Sagittalis.

The bastard futures.

The first.

The Bastard futures are so called, because they be not so euident and conspicuous as the former, or rather, because they belong to the kind of seame which is plaine, lying as the scales of a Fish, one aboue another. Some reckon foure, others five, we with *Banquine* will account sixe. The first is at the sides of the cauities of the Temples on each side one. [tab. 7. F, G, H] It runneth with a circular passage vpward from the root of the mamillary proceffe and passeth downward vnto the basis. [tab. 7. fig. 6, from F, G, H, to Ω] These futures are not made by coniunction, but rather by superapposition, so that the Bone of the *Synciput* is by little and little attenuated like the plate of a mayle Iacke or scale of a Fish, and lyerh ouer the temple Bone. And therefore they are not simply called sutures but *Squamosae agglutinationes*, and *Squamiformes suturae*.

Now the reason why Nature ioyned the Bones of the *Synciput*, and the temples together like scales was, because she determined to place in the laterall parts of the temple bones the small bones of hearing, for which end she stood in need to make the bones of the temples hollow,

TABVLA VII.

FIG. VI.

VII.

hollow, whereas if both Bones had beene thicke there had beene no roome for the cavity, and beside the head would haue beene too heavy. Wherefore out of the great Bone of the temples being attenuated, is formed a cavity for the bones of hearing, and the other bone of the *Synciput* was also made thin, that it might more fitly be ioyned to the temple Bones. These two sutures do ioyn together on the foreside the temple bones with the wedge-bone; [table. 7, figure 6, N with α] but behind and aboue with the Bones of the *Synciput*.

The fift, or the second bastard suture [ta. 7, fi. 6, b] runneth likewise obliquely downward at the sides from the top of the former [ta. 7, fig. 6, from H to g] vnto the beginning of the first common suture; [at g] and this may be called *Cuneiformis*, the suture of the wedge-bone; for on the vpper part it ioyneth the wedge-bone with the Bones of the *Synciput*, on the lower part with the bones of the forehead.

The sixt suture [tab. 8, fig. 9, MM ta. 9, fig. 10, f] is on either side at the basis of the head; oblique also and continuall with the *Lambdall* suture, and runneth from the extremity of the same close by the roote of the mammillary proceffe through the middest of the stony bone obliquely inward to the basis of the head, where it is ioyned to the first rackbone as farre as to the transuerse line; but because it doth not so exactly expresse the forme of a suture, but seemeth rather a simple line, therefore some haue called it *Lambdoides Harmonialis*, others *Lambdoides inferior*, and *Galen* an additament of the *Lambdall* suture; and this suture or line is common to the Additament of the nowle with the lower part of the temple bone and the Organ of hearing. In children it is very manifest but in growne bodies by degrees it vanisheth away so that in old men there is no remainder or shew of it.

The seuenth suture [tab. 8, fig. 9, nn. tab. 9, fig. 10, t] is a line in the middle of the basis of the head which runneth on either side ouerthwart with a short course till it end into the chinke or rift which is common to the wedge-bone with the temple bone. This is common to the Additament of the nowle with the wedge-bone, and ioyneth together the end of the *Lambdall* suture.

The eight [tab. 9, fi. 10, uu] is most conspicuous on the inside of the Scull. It runneth ouerthwart on both sides in the forepart thereof, and reacheth to the lower angles or corners of the spongy bone and the cavities of the Nostrils. It is common to the forehead with the fore-part of the wedge-bone. Moreover it separateth the spongy bone on euery side from the forehead bone, which seeme rather to be ioyned by *Lineall harmony* or *Cementation* then by suture.

The ninth [tab. 9, fig. 10, from u by R I vnto x on the left side] on the outside almost in the middest vnder the spongy Bones of the Nostrils appeareth foure square, and runneth obliquely according to the forme of the wedgebone, so that it is common to the spongy bone as it is referred to the Scull: on the backpart with the wedge-bone, on the forepart and in the sides with the forehead bone: and these are the six bastard sutures which with the three true sutures make nine proper sutures of the Scull.

The Sutures which are common to the Scull with the bones of the vpper Iaw whereby the processes of the bones of the Scull are fastened on the outside are accounted five.

The first is in the outside of the eye-brow, [ta. 7, fig. 6, 7, gg ta. 8, fig. 8, R; fig. 9, g,] and runneth outward from the end of the fift suture and the second common suture, and expresseth the right forme of a suture indeed, and it is common to the bones of the forehead and the first bone of the vpper Iaw.

The second which *Archangelus* maketh a proper suture of the Scull and *Columbus* accounteth for the sixt, appeareth in the vtter and laterall part of the orbe of the eye, and as if it were double is distinguished with a long common perforation; aboue it runneth downward [tab. 8, fig. 8, from S to Q, and fig. 9, to d. table 7, fig. 7, to d] from the outside of the orbe of the eye and the cavities of the temple bones vnto the foresaid perforation, and becommeth common to the wedge-bone with the first bone of the vpper Iaw, which maketh the outward angle; below it runneth directly downeward at the sides of the Pallate and the cavity of the Nostrils from the foresaid perforation euen vnto the roots of the teeth, [table 8, figure 9, from d to e] and is common to the wedge-bone with the fourth and sixt Bones of the vpper Iaw.

The third, which *Columbus* accounteth for the eight, is seated in the inside of the orbe of the eye and the cavity of the Nostrils, and runneth obliquely outward from the roote of the eye to the top of the Nose, [table, 8, fig. 8, R S T V X Y Z] and is common below, by a short

See this description, lib. 7. cap. 4.

short cut to the protuberation of the wedge-Bone with the third Bone of the vpper Iaw; the rest of his passage ioyneth the outward table of the forehead-Bone, with the second, third, fourth and fift Bones of the vpper Iaw.

The fourth.

The fourth belongeth to the Yoake-Bone, and runneth obliquely through the middest thereof, [tab. 7. fig. 6. r. ta. 8. fig. 9. r, fig. 8. p] and ioyneth the proceffe of the temporall Bone with the proceffe of the first Bone of the vpper Iaw.

The fift.

The fift is below in the cavity of the Nostrills, and runneth [tab. 8. fig. 9. under $\equiv$] from behinde forward betwixt the Processees called the *Bats-wings*, and is common to the wedge-bone, with the partition of the Nostrills. It is also to be obserued that all the coniunctions of the Bones of the head, which outwardly are sutures, on the inside do rather seeme to be ioyned by *Harmony* or *Cementation*, then by suture: on the contrary, saith *Eustachius*, in the Scull of an Ape they are each where so obscure, that for the most part they do not deserue the names of sutures. In some men also they are greater and more loose, in others smaller and more compacted.

The first sort are lesse troubled with paines in the head from internall causes, albeit *Celsus* in the first Chapter of his 8 booke, is of another mind; neither ought any man to wonder much thereat, because Anatomy in his dayes was but in the Infancy, and beside, that kinde of learning among the Romans was but geazon: the other whose sutures are more compacted, are obnoxious or subiect to continuall and great paines of the head, because the footy excrements are retained, which with their acrimony or sharpnesse doe goad the membranes, and with their abundance distend them.

The vses of the sutures.

The vses of these sutures are; first to be vents of the braine, that the thicker and footy excrements might exhale. But this was not the onely vse, for then the Scull might have been bored through with small perforations to haue serued that turne; but it was necessary that the *Dura meninx* should issue forth and be suspended to the Scull, lest the hardnesse thereof should presse the braine or the ventricles therein: beside those Filaments or strings doe make the *Pericranium*, and the *Periostium*. Furthermore, the sutures were made for the ingresse and egress of vessels for the nourishment and life of those parts.

Fourthly, that if at any time the head should happen to be broken, the fracture might not run through the whole Scull, but stay at the end of the fractured bone. Otherwise if a fracture were made in the forepart, the fissure or cleft would passe in the continuation of the Bone vnto the hinder part, as it will doe in an earthen pot. Finally, Nature found it needfull that some parts of the scull should be thicker, others thinner, some of one forme some of another; and therefore she thought it fit, rather to make it of many Bones, and to ioyne them together by sutures, then to make it of one onely Bone, which must haue had so great variety of parts. We may also adde with *Galen*, in the 22 chapter of the 13 booke, of his Method, and *Falopius* maketh it the 7 vse; that medicines which are to bee applyed outwardly might better enter into the braine and affect it. And thus much of the sutures.

The

TABVLA VIII.

FIG. IIX.

IX

The substance of the Scull varieth according to the age of the party. For in children new borne it is very soft, afterward it is gristly and membranous, especially about the commissures or seames [ta. 3, ta. 4, fig. 1, betwixt a and b, especially ta. 4, fig. 2, betwixt a and a] and in the vpper and middle part of the head; so that in some children till they haue passed ouer some yeares it will yeeld to the compression of a mans finger. And this tenuity or softnesse of the Scull was very necessary, both to make the birth of the infant more easie, as also for the growth of his head.

The substance
of the Scull.

But in growne bodies it is altogether bony for more strength; yet not thin, for then the parts contained vnder it would not haue been so wel secured, for a light violence would easily haue penetrated through a thin bone: nor yet fast and thicke, for then it would haue beene too great a burden; and therefore it was made neither fast nor thin, but thicke, rare and cauer-nous or full of holes. [ta. 9, fig. 11, 12, L ta. 10, fig. 14, c] Thicke for security and strength, and rare that it might not be a burden, porous also for Transpiration.

It is made of a double scale [ta. 10, fig. 14, a o] which some call *Diploas* or *Laminas*, we will call them Tables, which are most manifest in the bone of the Forehead, in the Temple-bones, in the Wedge-bones especially about the browes, or where the Scull was to be made thicke, as aboue where there is no flesh; below in the Basis especially about the perforations and the cauities to strengthen them. The Tables although they be hard and somewhat thicke, yet the vtter may sometimes be eaten away by the French discale, and the Patient recover notwithstanding.

The double
table.

Betwixt these Tables [ta. 10, fig. 14, betwixt a and o e] there is a substance which some haue compared to a Pumy stone, fungous and fistulated manifold, not onely to make the Scull the lighter, but that in the cauities and pores thereof a marrow might be contained, in which marrow the bloud and spirits which are powred into it out of the veines and arteries thither ariuing, is boyled for their nourishment, and this the Anatomists call *Meditullium*. In other parts although it be thin, yet is it hard and solid, as about the Temples where it is very thin indeed and giueth way to the Temporall muscles, in the cauity also of the eye where notwithstanding aboue and below it is duplicated.

The outward surface of the Scull is almost euery where equall and smooth, least it should hurt the *Periostium* wherewith it is compassed: yet in the margents or edges of the forehead bone, and aboue the cauity of the eyes it buncheth somewhat out for more strength: againe, at the sides of the Temples, the bones are compressed for the behoofe of the Temporall muscles, and in the Nowle it is exasperated with small knots or bunches made for the insertions of the muscles. The lower side or the Basis is very vnequall, and rough by reason of the many processes, cauities and swellings of the Bones, all which we shall make mention of in their particular History.

The surface.

The *Internall* cavity is also for the most part smooth, that the *Dura meninx* whereby it is compassed might not be offended. In the top as it were of the Helmet it hath shallow cauities, in the forehead bone and the Bones of the *Sinciput*, whereto the *dura Meninx* doth grow, and inscriptions also or lines for the courses of the veines: but below there are diuers productions, extuberations, and small bosomes made to receiue the different figures of the parts of the Braine, the After-braine and the instruments of the Senses.

The inner
cavity.

Both Tables are perforated with many small holes, thrilled not in order but wildly and as it were at aduenture, and those transuerse or oblique, through which small veines and arteries do passe into the cauity of the inner bones and the *sinus* of the *Dura meninx* or hard membrane.

Perforations.

Moreouer the small cauities or dens that are in either Table doe make way for the Transpiration of subtile and thin vapours, which if they be retained do breed giddinesse and other diseases. For the head is set aboue the rest of the parts as a rooffe vpon a house that is kept hot but without a chimney: whose rafters, because the smoake hath no vent, will become black and sooty. Beside these, most bones of the head haue their proper perforations, cauities, *Sinus* or bosomes & processes, of which we shall speak in the particular History of each bone.

CHAP. VI.

Of the proper Bones of the Scull.

THE Bones of the Scull are of two sortes: some belong to the Scull it selfe, some to the law, which is double, the vpper and the lower. The bones of the Scull in growne bodies are commonly 14. whereof some are proper others are common. The pro-
per-

The diuision
of the Bones
of the Scull.

per bones are in like manner of 2 kinds, some make the circumference of the scull, and these are commonly accounted fixe. The fore-head bone, the two Bones of the *synciput*, the Nowle-bone and the two Temple-bones. The other serue onely for the sense of hearing which likewise are six, three in each Temple-bone called the Hammer or Mallet, the *Stirrup* or Anuile, and the Stirrop. The common Bones of the scull are so called, because they are common to the scull and the vpper iaw, and these are two, the wedge-bone and the spongy bone. In children new borne the Bones of the scull are 22, two of the fore-head, two of the *synciput*, foure of the Nowle, two of the Temples, two Labyriaths, six of the Hearing, one wedge-bone, one spongy bone, and two without names.

The forehead
bone.

The first is the fore-head bone [tab. 7. fig. 6, 7 L. tab. 8. fig. 8, 11] seated before, for it maketh the forepart of the scull both aboue and below, and the whole forehead, and the vpper part of the orbe of the eyes. It is tyed aboue to the bones of the *synciput* [tab. 7. fig. 6, 1 K] by the *Coronall* suture; [tab. 7. fig. 6 C fig. 7, AB] belowe, partly to the bones of the scull as the wedge-bone, and on the outside to the bones of the Temples by the *scale-like* suture; [tab. 7. fig. 6 and 7 Ag] on the inside by the eight suture, [table 9. figure 10. T u] as also to the spongy Bone which it doth as it were encompasse by the ninth suture: [table 9. figure 10. from u toward K I] partly it is committed vnto some Bones of the vpper iaw, to the first in the vtter angle of the eye by the first common suture. [table 8. figure 8, R Table. 7. figure. 6 and 7 g] againe in the cavity of the orbe of the eye, to the second, third, and fourth bones; [table 8. figure. 8 S, T, V, X] and to the fift in the top of the nose [table. 8. figure. 8. XZ] by the third common suture.

This forehead Bone in growne bodies is but one, very rarely two [table. 3 c tab. 6. fig. 2 aa] though it be alwaies so found in new borne infants, distinguished by the *sagittal* suture; sometimes it continueth so to the seuenth yeare, but is afterward obliterated, the bones growing together. The figure of it is after a sort circular. The substance in a meane betwixt the Bones of the *synciput* and the nowle-bone. In infants that part where it is committed with the bones of the *synciput* and meeteth with the *sagittal* suture, is very thin, and in new borne infants [Table 9. figure, 11 R] but onely membranous, in growne bodies it is more thin and infirme in the cavity of the eyes and where it is ioyned with the eight Bone: in some places also it hath two transparant shels or scales. Toward the sutures it is thicker, that it might fasten more strongly with other bones, as also at the toppe of the nose and aboue the eye-browes, where it is diuided as it were into two partes to make a *sinus* or Denne.

The canities
thereof.

For betwixt the two Tables aboue the Nose in the Region of the Eye-browes, there are large canities for the most part two, [table 9. figure 10 and 11. L] one on the right hand, another on the left, which are distinguished with bony Fibres and small scales. Sometimes also, they are separated and encompassed with a greene Membrane, which containeth a soft medullous and as it were an oily body. In these bosomes there are perforations which determine partly into the cavity of the nosethrils, and one [tab. 9. fig. 10. aboue x] which endeth into the scull presently aboue the partition [tab. 9. fig. 10 x 1 a. 10. fig. 12 B] of the spongy bone, whereby the organs of Smelling are distinguished. But these bosomes are not found in those that haue flat faces and saddle noses, neither yet where the forehead is diuided. They were formed to make the voice more shrill, and thence it is that such as speake in the nose haue them not.

Why some
speake in the
Nose.

Their vses.

Again, they were made to containe the aire which is drawne in by the nostrils, that being alread it might first be conueyed to these bosomes, and from thence by degrees to the organs of smelling and so vnto the Braine to make alteration therein: they serue also when the Braine is affected to reduce it vnto his naturall state, as when for a moist Braine we appoint a Pomander wrought vp with Muske and Amber-greece; the Muske and Amber warmeth the aire that is drawne in by the Nosethrils and conueyed to these bosomes; and hence it is that oftentimes an odour that is drawne in by the Nosethrils remaining in these canities, is felt a whole day together in the top of the Nose. Some thinke, as *Archangelus* and *Piccolthominie*, that the matter contained in them somewhat like vnto Oyle, passeth through the perforation that is in the greater angle of the eye, and moisteneth the same, whereby it is made glib and his motion more quicke and speedy.

Pomanders.

The Den.

Beside these, there is also a Denne made of a double scale, the vtter scale maketh the vpper part of the Orbe of the eye [table 8. figure 8, aboue E,] and is plaine; the inner maketh the cavity aboue the eyes on either side [tab. 9. figure 2. Z] and is not plaine but hath inscrip-

tions

tions answerable to the winding convolutions of the Braine, whose protuberating portions it receiveth. A *Sinus* also runneth through the midst of this Bone, as farre as to the spongy bone, which was made for the third *sinus* of the *dura Mater*, to giue way vnto it that it should not be pressed by the forehead bone.

The perforations.

Holes it hath in the place of the Eye-browes, sometimes two, sometimes three, and three beside peculiar vnto it, one on the inside in the coniunction of the spongy bone with the forehead bone where it passeth into the sinus, of which we haue spoken before. Beside two on the outside at the middle of the browes, on either side one [tab. 8, fig. 8, AA] which is sometimes orbicular, sometimes long, and endeth into the orbe of the eye; thorough which a branch of the Nerue of the third coniugation is transmitted out of the orbe of the eye to the muscous skin of the forehead, haply also vnto the Muscles of the eyeliddes, whence it is that oftentimes when a man rubbes his forehead he will sneeze vpon it.

Finally, the forehead bone sendeth forth two processes, one vnto the lesser, another to the greater angle of the eye, which make the vpper brimmes of his orbe: and so much of the forehead Bone.

His processes.

The bones of the *synciput* are so called, saith *Arch. Angelus* of *our before*, and *Caput the Head*, because they make the anterior or forward part of the head. In Greeke they are called *ὀστέα βρεχυνάσια*, which word *Eustathius* vpon *Homer* acknowledgeth to be given, because in Infants that part is not onely tender but very moist: or rather saith *Bauhine*, because thereunder lyeth the moist and soft Braine. They are called in Latine *Ossa verticis*, because they make the heighth or top of the head: [ta. 7, fig. 6, IK] also *Parietalia* the Wall-bones, and by *Volcher*, the *Bones of Reason* or *Discourse*.

The Synciput.

They are two ioyned together in the midst of the length of the head by a suture common to them both, called *Sagittalis*: [ta. 7, fig. 6, A] and so ioyned make the vpper part of the scull, as also the sides for the most part as farre as to the eares. They are fastned also to the adjacent Bones, on the fore side to the forehead bone by the coronall suture, [ta. 7, fig. 6, AB] behinde to the *Occiput* or *Nowle* by the *Lambdall* suture [ta. 7, fig. 6, D e] on either side to the Bones of the Temples by the scaly sutures, [ta. 7, fig. 6, G F H] and finally to the wedge-bone by a part of the fift suture. [ta. 7, fig. 6, and 7, H, A]

Their forme is almost foursquare and almost equally thicke, sauing that they are attenuated where they are ioyned to the Temple-bones.

Forme and substance.

Their substance in growne bodies is hard and solid, yet in respect of other bones very rare and weake, and this haply is the reason why wounds in the *synciput* are most what mortall. In infants (for I speake not now of Beasts but of men) the anterior part of these Bones where the *Sagittall* suture is ioyned with the *Coronall* [Table 7, figure 6, B N] is Membranous and hardneth by degrees, and the two Bones do grow together and are indurated last of all the Bones of the Head, and some haue thought as *Aristotele* and *Pliny*, that it is not possible children should speake, before the whole scull bee become Bony.

Because of this softnesse when the Bones are not yet so well growne that they can cover the whole Braine, you may obserue about the crowne of the head as it were a breach or Den, [tab. 9, fig. 11 T. tab. 6, fig. 11, aa] which the Arabians call *Zendeck*, the Barbarians because of the moysture and pulsation do call it *Fons pulsatilis*, the beating fountaine. Others call it the *Fontanel*, and indeed in that place at this day we vse to apply Cauteries, and the Ancients vsed red-hot frying pans in fits of the Apoplexy, for so I may call the instruments with good warrant: if you would know the very place of this coniunction in a liuing body, let him lay the roote of the palme of his hand betwixt his browes, and the middle finger will designe the iust place.

The breach betwixt them.

These Bones haue on the inside superficial cavities or small Bosomes, to which the *dura Meninx* growes, as also inscriptions [tab. 9, fig. 10, and 11, SS] for the vessels which run from the internall iugulars through the thicke Membrane of the Braine. They haue also some smal perforations, especially outward at the sides of the *Sagittall* suture which perforate the bone from one side to another, and transmit small veines for nutrition.

The Bone of the *Occiput* or the *Nowle*-bone [table 7, figure 6 and 7 M, tab. 8, figure 9 M M] is called *Occiput*, of *Oc* for *Ob* and *Caput*, because it is behind the head. Some call it *Os basilare*, the Arabians *os Prora*, and *os Memoriae*, as if the memory were seated in it. The situation of it is behinde, and it maketh the backward and lower part of the Scull and the middle

The Nowle-bone.

dle part also of the Basis. *Platerus* saith it is alwayes one, but saith *Baubine* I haue a Scull wherin it is made of three bones, and *Eustathius* maketh mention of the like.

In children till they come to the end of the first yeare it consisteth of foure bones, one above, which maketh the greater part of the capacity, and in some bodies is diuided in the middest by the sagittall future. Another below, vnder the great perforation which they call his additament; at the sides of that perforation are the 2. other very thin bones and gristle-bound or vnited by *Synchondrosis*, for they are deuided by lines filled with a gristly substance; which becomming in time harder is turned into a bone. It is fastned about to the bones of the *sinciput* [table 7, figure 6, I K] by the *Lambdall* future, [table 7, figure 6, C D] at the sides of the Temple bones by the additaments of the same *Lambdall* future, or by the sixt future, [table 8, figure 9, m c] and in the middest of the wedge bone [table 8, figure 9, 00] by a transuerse line or future, or by the seuenth future which is common to it with the wedge bone [table 8, figure 9, n n.]

His connexion.

Figure.

Substance.

The figure of it is almost round or rather *diangular*, consisting of two circular lines which end into sharpe determinations.

The substance is hard and fast about all the bones of the Scull, and thickest as the *basis* where it is without flesh, and where two *sinus* of the *Dura meninx* are ioyned, [table 9, figure 10, vnder fgh] for it behoued well that it should be stronger then the forehead bone, because it is behind where it could not so well haue been attended vnto. At the sides of the great perforation [table 8, figure 9, H. table 9, figure 10, d] it is somewhat thin, (*Aristotle* saith the thinnest of all bones, but he mist his marke) and without any canities or small dens therein, but in the middest (to strengthen it the more because of his thinnesse) there ariseth and runneth a long prominence [tab. 9, fi. 10. at h] throughout, to secure it if by chance a man should fall backward.

Sinus nine.

It hath nine *Sinus* or Bosomes, 7. on the inside, of which two are partly oblique and partly transuerse: on each side one which climeth obliquely vpward and backward through the temple-bones, [tab. 9, fig. 10 from b towards q] presently runneth ouerthwart [tab. 9, figure 10, and 11. about h] and so they meete in the middest of the Nowle. They are made to receiue two *sinus* of the *Dura meninx* that they should not be compressed by the bones of the Scull.

The third *Sinus* is right, straight, and from the congresse of the former runneth directly vpward, and vnder the *sagittal* future, and the middle of the forehead bone attaineth vnto the spongy bone, [tab. 9, fig. 9, at h] and this *Sinus* was exculped or grauen in the bone for the third *Sinus* of the *Dura meninx*.

Their vse.

There are two other bosomes seated about the transuerse, and distinguished by a right line. Their vse is the better to receiue the Braine, which is double. There are yet two other large *Sinus* in the *Basis* below the transuerse, [tab. 9, fig. 10, g] which receiue the protuberations of the After-braine, and these are the seuen *Sinus* on the inside.

On the outside there are two semicircular, made to receiue the two *anterior* processes, [tab. 8, fig. 9, ll]

Their perforations.

The perforations of the Nowle-bone are five: the first [tab. 8, fig. 9, H. tab. 8, fig. 10, d] is in the middest of the *Basis* of the Nowle. The largest of all the inward holes of the head; it is round but somewhat long, through which the marrow of the braine falleth into the spine. It hath also two other perforations [tab. 8, fi. 9, F. ta. 9, fig. 10, b] common to it with the temple bone, on either side one betwixt the head of the Nowle [table 8, figure 9, betwixt l and i] and the appendix *Styloides*. These are notable and long perforations, and seeme as it were double, for through it in the lower and vtter part doth passe the greater branch of the internall *Angular* veine, and the lesser branch of the sleepey artery: againe, through the vtter and inner part passeth the sixt coniugation of Nerves.

Two other proper perforations it hath [tab. 8, fig. 9, tab. 9, fig. 10, c] which are neare vnto the first, running obliquely inward and are orbicular: yet sometimes they are long for the transmission of the seuenth coniugation of sinewes which is presently ioyned to the sixt; sometime also it transmitteth a veine and an artery. Sometimes there is yet found another perforation on either side in the vtter part of the head of this bone [tab. 8, fig. 9, B] which is not very large because it runneth a long course before it get within the Scull. Some thinke through it there passeth a veine and an artery which did climbe vp the transuerse processes of the Rack-bones: but saith *Baubine* we finde this perforation wanting oftentimes on one side, sometimes on both, and then these vessels passe through the two holes last before mentioned.

On

On the outside at the Basis, the Nowle-bone is rough and vnequall, as well for the Original, as for the infertion of the Muscles and ligaments.

His processes or heads (for so we called them even now, and according to *Platerus*) are two, [*tab. 8. f. 9. ll*] broad before, and in infants they haue an Appendix covered also with a gristle, and protuberation more inward then outward, which processes are inferted into the Sinus of the first rack-bone to helpe the motion and articulation of the head. On the backside there ariseth a small processe which is receiued by the first rackbone.

Finally, in dogs from the nowle bone proceedeth another triangular bone sinuated, which goeth betwixt the braine and the After-braine.

The temple bones called *ἰσχυρότερον*, are called by diuers names, *Ossa lapidosa*, *Saxea*, *Parietalia*, *Dura*, *Arcualia*, *Squamiformea*, *Squamosa*, *Menäosa*, [*tab. 7. f. 6. and 7. N. tab. 8. f. 9. TT*] their principall part is about the sides neare the eares, part of them also is in the basis. In growne bodies they are two, on each side one, but in children each bone by the interposition of a gristle is parted quite through the auditory passage. The footsteps of which diuision doe yet remaine at the entrance of that passage. They are conioyned aboue with the bones of the *Synceput* by a proper Scaly suture, [*tab. 7. f. 6. and 7. G. E. F*] sometimes also with the forehead bone below, and on the inside with the Additament of the nowle-bone by the sixt suture; [*tab. 8. f. 9. mn*] in like manner with the wedge-bone: before that is, at the sides, it is ioyned by that suture by which the stony-bone is annexed to the same wedge-bone, [*tab. 7. f. 6. from a to H*] but in the basis on the outside where the cleft is, they are parted asunder. [*tab. 8. f. 9. from n to o*] Finally, they are ioyned with the first bone of the vpper iaw; [*tab. 7. f. 6. r*] I meane their processe which is called *Iugalis* or the yoke (for that is a processe of the temple bone) by the fourth common suture.

The temple bones.

The Con-
nasion.

Their figure is aboue ample, round and semicircular, but below it hath no shape but seemeth like a rude rugged and vnequall Rocke.

Their figure
and substance.

The substance is also full of variety, for at the basis they are thicke and rough like Rocks whence they are called *λιθονειδῆς*, *Petrosa*, *The rocky or stony bones*. Ascending they are by degrees attenuated, so that they were not so thicke at the basis, but they are as thin at the top, yea transparent; especially where they giue way to the temporall muscle, and like scales are adioyned by the second kinde of suture to the bones of the *Synceput* which in the descent are attenuated to receiue them: and though the height of the temple bone be but thin in respect of his basis, yet it is harder and faster then the bone of the *Synceput* vnder it, to which it is a kind of defence, and therefore cannot be broken without danger of death, although *Columbus* make mention of two children cured of fractures in that place, the one at *Padua*, the other at *Rome*.

Moreouer if these bones had beene equally thicke throughout and not attenuated toward the top, their very waight, if nothing else, would haue beene burthensome. On the outside they are solid, smooth, and plaine; on the inside because of the conuolutions of the braine it hath many rising inscriptions. Againe in the basis of it we shall finde one Appendix, three Processes, eight Perforations, and two Sinus or cauities, of which we will speake in order.

Parti.

The Appendix is sharpe, long, and slender, and a little incurued like a Cocks spur. [*tab. 7. f. 6. and 7. i. tab. 8. f. 9. ii*] It is commonly called *Styloides*, sometimes *Belenoides*, *Graphoides* and *Plectrum*, that is, the *Bodkin*, the *Needle*, the *Pen*, and the *Cockspur*. In children it is gristly, in growne bodies solid and hard, but because it sticketh farre out, a little thing will breake it off, which is the reason why we finde it so seldome in Sculls gotten out of the ground, yea a little seething will make it fall away.

Appendix.

From this Appendix proceed the muscles which go vnto the bone *Hyois*, the tongue and the lower iaw to draw them downeward, yea the bone *Hyois* it selfe groweth thereto by the interposition of a ligament. So much of the Appendix.

The first processe is on the outside blunt and dull tending downward on each side one, which because they are like the nipple of a Cow are called *Mastoides*, *mammillares*. [*table 7. figure 6. and 7. K. table 10. figure 8. M. fig. 9. K*] It is a thicke processe, spongy within and somewhat hollow, it may be for more lightnesse, and it serueth for the infertion of the muscles which bend the head; wherefore it is rough and like a Rocke. The second processe runneth forward from the hole of the eare to the processe of the first bone of the vpper iaw to helpe to make the bone called *Iugall* or the yoke bone, for these two processes one of the Temple-bone, the other of the first bone of the vpper iaw being ioyned with an oblique

The Bones of
Hearing, and
the Cavities
of the Stony-
bone.

oblique future doe make the fashion, as it were, of a Bridge, or of a Yoke. [tab. 7 f. 6 & 7, V X, ta. 8 f. 8 at P] The third proceffe is on the inside [ta. 9 f. 10 a] and stony, swelling out in length; wherein there is a triple or threefold cavity. The first is called *Tympanum*, the *Drum*, the second, *Labyrinthus*, the *Labyrinth*, the third, *Cochlea*, the *Snailshell*; where also there are three Bones of hearing, all which, because they were made for that sense we haue handled particularly; the cavities of this stony-Bone in the 20, 21, and 22 chap. of the 8 Booke, as also the three bones of hearing in the 18 chap. of the same Booke, where he that listeth may find abundant satisfaction, at least so farre as we could serue his turne, for wee haue handled them there very particularly. The third proceffe in Infants is called, *The Bone of the Labyrinth*, because it lyeth vnder the scaly Bones, and is so straightly fastned vnto them that at length they vnite; so it changeth his name, and is called the interior proceffe of the Stony Bone. So much for Processes.

The perfora-
tions.

The Perforations are of two sorts, fixe externall and two internall, which doe let something in, or send something forth, or both. The first externall perforation which *Platerus* calleth, *The third of the Temples*, and the first of *Hearing*, [ta. 8 f. 9 y] is very large betwixt the Mammillary proceffe and the Iugall or Yoake-Bone, because it intromitteth or giueth way to the entrance of ayre and sounds. It is called by a proper name, *Meatus Auditorius*, the hole of *Hearing*.

The second perforation which *Platerus* accounteth for the first of the Temples, is in the backside, neere to, but behind the Mammillary proceffe [ta. 6 f. 9 x] and entreth into the cavity of the Scull at the transuerse and round side of the *Lamddal* future.

This perforation is sometimes wanting in one side sometimes in both, but when it is there, a branch of the externall veine passeth through it.

The third perforation which *Platerus* accounteth for the second of the Temples, is at the stony proceffe [tab. 8. f. 9 X] vnder the appendix, called the *Bodkin*, or *Styloides*. It is a great hole, vnequall, and runneth oblique from behind inward and forward, through which the greater branch of the Sleepy artery runneth obliquely vnto the fist hole of the wedge-bone, and from thence into the Ventricles of the Braine; by it also issueth a portion of the third Coniugation of sinewes. It was bored slante or oblique, that it might more safely passe without breaking from behind forward. Some thinke the cause of the obliquity was, that the spirituous bloud might there make a certaine stay.

The fourth hole, which *Platerus* calleth the fourth of the Temples, and the second of *Hearing*, is likewise oblique, double and short. [tab. 8 f. 9 V] It intromitteth the Iugular veine, and sometimes transmitteth a small branch of the Auditory Nerue.

The fift, according to *Platerus*, the fift of the Temples and the third of *Hearing*, is betwixt the Mammillary proceffe, and the appendix *Styloides*, a round perforation, and determineth into the long Canale. It intromitteth the sleepy artery, and giueth way vnto the egress of a Nerue.

The sixt, according to *Columbus* the fift, is betwixt the Nowle and the Temple-Bone, great and vnequall, and bored for the egress of the sixt Coniugation of sinewes, and the ingresse of the Internall Iugular veine vnto the Braine.

The seuenth, the sixt according to *Platerus* of the Temples, and the fourth of *Hearing*, is bored in the backside of the proceffe, [tab. 9 fig. 10 a] it is long, and as it were ouall, dilated by degrees, and runneth with a blind passage (from whence it is called *Foramen cecum*, the blinde hole) into the *Labyrinth*: into this hole the Auditory Nerue of the fift paire doth passe.

The eight, according to *Platerus* the seuenth of the Temples, and the eight of *Hearing*, is in the foreside of the proceffe; [tab. 9 f. 10 against a] a narrow perforation, and rugged like a rift, and it transmitteth from the Organ of *Hearing*, a small Artery into the Capacity of the Scull. And thus much of the perforations.

The Sinus.

The *Sinus* or Cavities of the Temple-bones are two. One outward [tab. 8 f. 9 b] betwixt the hole of *Hearing*, and the proceffe of the Yoake-bone: it is a long Cavity, transuerse and crufted ouer with a Gristle, and into it the longer proceffe or the head of the lower Jaw, is inserted and articulated, and this *Sinus* saith *Columbus*, *Galen* in his Booke *De Ossibus*, hath not rightly described. The other bosome or cavity is inward, at the backside of the proceffe, long and oblique, and common to the Temple-bone with the Nowle-bone. [tab. 9 fig. 10 from b toward i] And thus much of the proper Bones of the Scull.

CHAP. VII.

Of the Bones that are common to the Head and the vpper Iaw, that is to say, of the Wedge and spongie bones.

THE first Bone that is common to the Head and to the Iaw, is called *Sphenoides*, either because it is like a Wedge, sharpe above and thicke below; or rather for that like a Wedge it sticketh betwixt the Bones before named and those of the vpper Iaw. The Interpreters of the Arabians call it by diuers names, *os Paxillare*, *Colatory*, *Basilare* and *Canilla*. It is seated in the middle of the basis of the Head, yet so as that it toucheth almost all the bones of the head and the vpper Iaw. It is ioyned before, to the fore-head bone by the eight transuerse suture, [tab. 9, fig. 10, from T to u] to the spongie bone on the inside by a portion of the ninth suture; [tab. 9, fig. 10, at the middle u] On the outside at the cavity of the nostrils, to the partition by the first common suture; [tab. 8, fig. 9, neere z] behind, to the additament of the Nowle-bone by the seventh suture; [ta. 8, fi. 9, nn] at the sides to the temple bones by the scaly suture; [ta. 7, fig. 7 a] to the angle of the Bone of the *Synceput* by the fifth Suture, [tab. 7, fig. 6 and 7 from H to A] and to the forehead bone by the same suture. [from A to g.] It is also ioyned by his eminences or processes to the bones of the vpper Iaw, as on the inside, with the orbe of the eye, with the third Bone of the Iaw by the third common suture. In the outside with the first, fourth and sixth Bones of the vpper Iaw by the second common suture. [ta. 8, fig. 8, from S to Q, and fig. 9 from d to e]

The Wedge-bone.

Connexion.

In growne bodies it is but one bone, yet at first is compounded of foure Bones, with a Gristle betwixt them, which (saith *Falopius* in his Obseruations) do not appeare distinguished after the seventh month but are vnited. The first of these foure is the basis, in the middle almost of the head separated by a transuerse line from the end of the additament of the Nowl-bone, and it containeth the Pituitary Phlegmaticke Glandule, and because it is like a saddle, is called the saddle of the Wedge-bone. [tab. 9, fig. 10, B]

His parts.

The second part of the wedge-bone hath no name, and is destined to beare vp the vnition of the Opticke nerues, [ta. 9, fig. 10 D] and is coupled to the first with a plentiful gristly substance; toward the palat there is in it a bony naile, whereto is fastned a long and broad bone which is gristly in the originall, and is like to the Cowlter that ruaneth before the Plowshare. The third and fourth parts of this bone are two processes, on either side one like to wings [tab. 8, fig. 9, char. 1, 2, 3, 4] Wherefore because this bone is made vnequall, with many processes both within and without, it was called by the Ancients *πολυμορφον*, *Seare-shape*, according to the Lincolnshire Dialect.

The substance thereof is in the Basis dense and fast, partly because the head lyeth vpon a basis, and therefore the Barbarians call it *os basilare*, partly that it should not be hurt by the excrements that fall downe. In young bodies it is solid, but in growne hollow in the midst, for the hollownesse is made of the solid matter distended; for as he that out of a little quantity of glasse bloweth a great Violl, so Nature according to the vse she had of this bone, first made it dense and solid in children, and then dilated that density into a hollownesse, which is large and couered with a hard and fast scale or shell not at all perforated; as for the inner part, there the substance is not so solid but somewhat spongie.

His substance.

It hath many processes, some externall, some internall; within two on either side, which they call *κλινωδεις*, because they expresse or resemble the lower part of a bed or a Table. [table 9, fi. 10, aa] The two forward of these are the larger & thicker, and from a broad basis do end in a sharpe Cone. The two Posterior in some bodies doe not bunch out at all, but are euen like a Wall, and therefore some haue taken it for one Processe. Their vse is, that the *Dura Meninx* might be more strongly fastened vnto the Skull.

His processes.

The outward processes are double: before, one on either side neere the partition of the Bones of the Nostrils and the Palat, in that place where it is ioyned with the vpper Iaw. And these processes are likened by Anatomists to Bats wings, and therefore called *μεγασδεις*, for they are thicke and yet end into a notable thinnesse, almost as sharpe as the edge of a Knife. [tab. 8, fig. 9, char. 1, 2, 3, 4. tab. 10, fig. 12 HH] They serue for a seate and a couering to the muscles that lurke within the mouth: wherefore in the midst of them there is a deepe and long cavity from which the muscle taketh his originall, and whereby it is defended. On the backside, the bone hath two small points bearing outward the *Styloides*. The anterior of these is blunt, and from it the first muscle of the Chops doth arise; the poste-

rior

His bosses.

sterior is rough and sharp, from whence issueth the five paire of muscles of the lower iaw or very neare vnto it. Finally, there issueth another processe from the middle edge thereof which diuideth the pallat into two. There are also bosses or cavities insculped in this bone. On the outside of the *wingy* processes as hath bin said: on the inside one *anterior* and vpper, which is transverse and long [tab. 9 fig. 10 at C] and prepareth a place for the coniunction of the Opticke nerues. Another *posterior* and lower, almost foure-square, broad, and smooth, very like vnto a saddle. Hitherto the necke of the *Tunnell* reacheth, and in it the glandule which receiueth the phlegme, hath his abode, [tab. 9 fig. 10 E] out of which the same moysture floweth after ward into the pallat and the nostrils: for from this cavity or bossome, at the sides on either hand doe issue two canales very shallow.

The vpper of these [t. 9 f. 10 F] doth attaine forward to his second perforation, through which perforation the teares distill into the eyes, and the phlegme runneth either vnto the Nose or vnto the Chops, through the fourth perforation; through the lower [tab. 9 fig. 10 O] the phlegme is thought to distill into the chinke [tab. 8 fig. 9 N] which is seated betwixt the stony bone, the bones of the *Synsippiut*, and the wedgebone, and from thence into the Pallat.

His Cavities.

Cavities it hath, two at the sides of the forenamed bosses, common with it to the Temple-bones and the bones of the *Synsippiut*; on the inside concavous or hollow, on the outside conuex or embowed. [tab. 9 fig. 10 SS] One also, and that notable, is in the *Basis* of this bone [tab. 9 fig. 10 vnder E] betwixt the surface which is toward the Braine, and that which is toward the cavity of the mouth. This cavity in children, is not found although the part be spongy for a whole yeare, in growne bodies it is hollow and scaley, sometime

See this description, tab. 4. lib. 7.

not distinguished, but spongy and made of diuers scales, sometime it is divided into two distinct [tab. 10 fig. 12 E] cavities [ta. 10 fi. 12 CD] which are great or little, according to the increment or growth of the Bones. This Cavity is covered with a fine and thinne membrane, as those cavities are which be in the forehead and in the cheekes. It is either empty (and therefore some haue thought it was made for the voyce, and that the bones might be the lighter) or in it is contained a viscid or tough phlegme. Vnder these is another small Cavity fundred into twaine by a partition: [table 10 figure 12 O] and from the former Cavity runne two holes vnto the nostrils, [figure 12 F] haply to giue entrance or entertainment to ayre, although *Platerus* saith, it containeth a medullous substance therein. It is couered on euery side with one continued scale, no where bored, or hauing issue but in the capacity of the nostrils: yet is this scale very thinne, and may easily be bored through with a sharpe pointed Probe. If in some bodies these cavities doe not appeare, then it is made within spongy or hollow like a Pumy Stone, ouer the surface of which porous substance are drawne continued scales.

His perforations.

5 in the orbe
of the eye.

It hath ten perforations, some in the orbe of the eye, others in the *basis* of the Scull. In the orbe of the eye five, three proper and two common with the vpper iaw. The first of these neere the processes

TABVLA IX.

FIG. XI.

which

which make the saddle, is circular or round [tab. 8 fig. 8 EE tab. 9 fig. 10 B] made for the transmission of the Optick Nerues, and above in the outside it hath (as it were) a little angle [ta. 9 f. 10 C] through which passeth one small veine vnto the eye. The second perforation bored in the vpper part, is not round, but like a semi-circular cavity, a slit or a long cleft ending into an acute angle, [ta. 8 fig. 8 G, ta. 9 fig. 10 G] but the lower part of it is somewhat long and orbicular. And of this perforation *Bauhine* vnderstandeth that of *Galen*, where he saith; That the wedge-bone is perforated like a Siue, as if his meaning were that this rift is like a Siue, through which the Phlegme doth distill; and fitter it was saith *Galen*, in the 11 *De vsu partium*, that it should transcolate or distill then fall directly through: Otherwise we should be continually spitting, and must haue held our mouthes open; and therefore herein *Vesalins* and *Columbus* were too apprehensue to find fault with *Galen*, whereas indeed they are rather to be found fault withall themselves, that they did not sufficiently vnderstand him, as we could make it manifest, if it were a fit place to dispute so nice questions in, but we follow our History.

Through this second hole passeth the second Coniugation of Nerues vnto the muscles of the eyes which arise thereabout: also, the third paire or the lesser part of the third coniugation which goeth vnto the skin of the forehead, to the muscles of the cheeks, and of the nostrils; which issueth partly by the hole of the fore-head Bone above the inner angle of the eye, partly through the fourth hole; thirdly, a notable branch of the sleepey Artery; fourthly, a veine entreteth into the cavity of the forehead, from the greater veine of the temples; fiftly thereby issue the watery humidities of the Braine, which are gathered together in the glandule, of which teares are made, and those get out of the cavity of the eye, from thence through the fourth perforation into the fist, and from the fist they fall into the cavity of the nosethrils. And these are the vses of the second perforation. The third is immediately vnder the forenamed rift. A little perforation it is and perfectly round, thorough which the lesser branch of the fist coniugation of sinewes is transmitted to the temporall muscle and to those that lurke within the mouth: sometime also it giueth way to the

TABVLA X.

See this Table with his description in fol. 443.

FIG XII

XV.

lesser roote of the third coniugation, which falleth out sometime together with the second paire. [tab. 8 fig. 8 H ta. 9 f. 10 H] The fourth perforation in the outside of the cavity of the eye towards the nose is long and large like a rift, and is common to the wedgbone with the fourth bone of the vpper law. It transmitteth out of the orbe of the eye small nerues of the lesser root of the third and fist coniugations, and phlegme or rheume with them, all which entred into the orbe by the second hole. [t. 8 f. 8 & 9 D] The fist hole lurketh in the root of the eye at the end of the fourth. It is a long, large and notable perforation, through which the rheume which fell out of the Scull through the second hole, and into the orbe of the eye by the fourth hole, is conueyed vnto the capacity of the nosethrils, [t. 7 f. 7 *] and these are the five perforations of the wedge-bone in the orbe of the eye.

In the basis also of the Scull it hath five perforations. The first within, at the side of the bosome where the Glandule is seated: a wide, short and orbicular hole it is which admitteth the great branch of the sleepey artery to the second hole of the templebone into the Scull. [tab. 9 fig. 10 X] The second is on the outside, somewhat long and large, which transmitteth the greater roots of the third and fourth coniugations of sinewes,

O 6 0 0 3

out of the basis of the Scull.

commonly so called. [tab. 8, fig. 9, Q, ta. 9, fig. 10 Q] The third adioyneth on the outside to the second, but is much lesse and round, made to admit the branch of the internall Iugular veine which entreth into the scull and into the substance of the *Dura meninx*; [ta. 8, fig. 4 R, tab. 9, fig. 10 R] sometime at the side of the sixth perforation we find small holes prepared to admit a branch of the foresaid Veine. [tab. 9, fig. 10 M] The fourth is at the Nostrils, a long hole and running directly outward, through which a branch is conveyed into the cavity of the nostrils [tab. 9, fig. 10 V] from the greater branch of the sleepe artery. The fifth and last perforation of the wedge-bone is in the palate at the extremity of the winged proesse: it is large and almost oval, that through it the third coniugation of sinewes and the fourth might issue: [ta. 8, fig. 9, u] The third into the tongue and his coate, to the teeth and the lips to giue them sense; the fourth to make the coate of the pallet. And thus much concerning the wedge-bone

Of the Spongy Bone.

The second Bone that is common to the Head and the Iaw, which *Vesalius* and *Columbus* make the eight bone of the head, Anatomists haue called *Ethmoides* or the *Syue*, not because it is full of holes and dennes, but because these holes are not direct (though some direct there be) but curved or writhen as are the holes of a Sponge. It is more truly called *Spongoides* or the Spongy-bone, which name *Hippocrates* gaue it, as *Galen* witnesseth in the 7 chap. of his 8 Booke *De usu part.*

Situation,

It is situated in the forepart of the scull before the *Meninges* and filleth vp almost the whole cavity of the Nostrils. It is ioyned to the middest of the forehead bone, [tab. 9, fig. 10, R] and is distinguished on the backside from the wedge-bone by the ninth future of the head, if that be not rather a harmony or Ccementation then a future; [ta. 9, fig. 10 above u] on the outside it determineth at the second bone of the vpper iaw, *Columbus* saith at the second and the third.

Figure,

The figure of it is like to that square that on one side is longer, on the other broader: but he that would see the true figure of the bone must take viewe of it in a child but of one year old, for afterward it cannot be seuered from the rest of the bones without breaking. At that age also a man may perceine how that which is accounted by *Vesalius* and *Archangelus* the third bone of the Iaw which maketh the thin but solid and plaine part of the orbe of the eye, and the Spongy bone of the nostrils which is oft eaten out by the French disease, and the Syue-bone, are all parts of one and the same bone. For, indeed there are foure parts of this bone.

Parts,

The first is the vpper proesse in the middle of the bone, long and triangular, ending in a sharpe point and resembling a Cockes-combe; sometimes it is thin and broad; sometime thicke and diuideth the whole bone like a partition: it distinguished also the Mammillary processes of the Braine. To this part also the third sinus of the *Dura meninx* which diuideth the Braine groweth very strongly. [ta. 9, fig. 10 * ta. 10. f. 12 B]

The second part of the Spongy-bone is on either side at the proesse where it maketh the cavity of the scull. It is throughout perforated like a Syue with abundant, small and oblique holes. [tab. 9, fig. 10, KI tab. 10, fig. 12, AA] In dogges these holes are much larger, whence haply it is that their smell is so briske and sharpe. It is compassed with a thin Membrane which is perforated like the bone, and that indeed was the reason why it was called the Syue-bone or the Collander.

The third part is a lower proesse opposite to the vpper which distinguisheth or separateth the vpper part of the nostrils.

The fourth part and the last like a sponge or a pumi stone is porous and full of smal cavities, whereupon the whole Bone is called *spongoides*. This part is seated in the vpper part of the nostrils, and accomplisheth or perfecteth the inside of the orbe of the eye. It is spongy and full of oblique perforations that the cold aire which we breathe in, or impure aire might not insinuate it selfe directly into the Braine vnbroken or vnaltred, whereby it might be too much refrigerated or otherwayes annoyed; for being a while retained in these oblique passages it receiues a mutation, and is made more like to the temper of the Braine. And here *Galen* in the seuenth chap. of his eight Booke *de usu part.* doth worthily commend the infinite wisdom of our creator, who hath disposed of all the parts of our bodies, as was most fit for our vse and preservation. This bone therefore is manifold: at the head perforated like a Syue, at the cavity of the nostrils spongy, at the orbe of the eye plaine and broad. And hence it appeareth that the substance of this bone is very thin thrilled, also manifold but finely and oblique, finely or with a small bore least any thicke body that flies in the aire should get into the braine.

The wisdom
of God well
obserued by
Galen.

The

The vse of the perforations is, saith *Galen* in the sixt Chap. of his 8. booke *de usu partium*, The vse of the perforations, that through them the ayre might be breathed in for the generation of Animall spirits: againe, that with the aire odours or sauiours might ascend into the braine, and therefore the Mammillary processses or the organs of Smelling doe run out hard vnto these perforations; hence it is that those that be troubled with the *Coriza* (we call it commonly the *Pose*) cannot smell, because these perforations are stopped vp with Rheume. There is also good vse of them in diseases of the braine, that the ayre being altered by medicines, and retained longer in these caviities, might worke more powerfully vpon the braine.

Galen in the place last before quoted addeth another vse. By these perforations saith he, when neede is, abundance of excrements may be suddenly and togetherward auoyded: so likewise saith *Laurentius*, but maketh it a secondary vse, yet *Platerus* denyeth that there can be any such confluence, vlesse it be vnnaturall or beside nature.

Finally, in the backside of this bone on either hand there is a semicircular rift or cleft, as if it were pinched with a mans nayles, which establieth [tab. 9, fig. 10, below K] the *Dura meninx* fastned thereto and perforated with diuers holes. And thus much concerning the spongy bone which is the last of the bones of the head or of the Skull. Now we proceede vnto the bones of the Nose.

CHAP. VIII.

Of the Bones of the Nose and of the Yoake bone.

HE Bones which make the cavity of the Nostrills are of two sorts: some which may be said to be proper to the Nose although indeed they be bones of the vpper iaw, others are common. The proper bones are three, two externall and the third internall, and these runne onely vnto the middle of the Nose, for the rest is altogether gristly.

The two externall bones which make the arising bony part of the Nose are one on each side, small and quadrangular, but one side is longer then another. These are thin but very solid, perforated with small and common holes and are portions of the fift bone of the vpper iaw, [tab. 8, fig. 8, =] which portion aboue is ioyned in a short cut by the third common suture with the forehead bone betwixt the browes. [ta. 8, fi. 8, z 7] At the sides they are vnited by a proper suture, *Archangelus* calleth it a *Harmony*, running along the side of the Nose [ta. 8, fi. 8, from e towards y] with the 4 bone of the iaw [ta. 8, fi. 8, B fi. 9, s A] which maketh the sides of the nostrills, the lower part of their holes, and the greatest part indeed of their capacity. Below they are vnited by gristles, wherefore at their end they are rough vnequall that the gristles and the bones might cleaue faster together. On the inside they are ioyned by another common line and cleaue fast vnto the partition of the *Syue-bone*.

The two externall Bones.

The third bone we said was inward within the cavity of the nostrills: broad it is and thin at the roote, but before and aboue thicke: it tendeth vpward to the holes of smelling and downward to the Pallat. This is placed betweene the two former and adhereth, yea is vnited to a processe of the *Syue-bone* or the eight bone of the head. [ta. 9, fi. 10, vnder x] It is called *Septum* or the partition, because it distinguisheth the cavity of the nostrills into two parts. [tab. 8, fig. 8 O] It is ioyned to the two former or the fift bone of the iaw by the first internall suture. [ta. 8, fi. 8, vnder f] On the foreside it determineth into the middle gristle wherewith it is vnited. At the inner hollownesse of the Nose toward the Pallat where this bone is seuered from the wedge-bone, it is deuided throughout his length by a broad rift, passeth throughout the Nose, and having his *Basis* which is thicke and broad bifurcated it lyeth vpon the wedge-bone, resembleth the share of a Plough [ta. 8, fi. 9, c] and his edge is sinuated or vnequall. Finally, it is ioyned on the inside to the fourth and the sixt bones of the iaw by the second internall suture. [tab. 8, fig. 8, g] These are those three we call the proper bones of the Nose.

The third internall.

The common bones are, first that which we called the spongy bone which cleaueth to the top of the roote of the Nose, for in the inside of the Nose at this bone there are found two fungous and spongy portions which fill the vpper cavity of the nostrills, and are made to assist the voyce and the smelling. Their forme is very diuers, but they seeme to be most like scales growing one vpon another. They are vnited with the *Syue-bone*, from

The common Bones.

whose

whose outward sides they issue, so that saith *Baubine* for my part I beleue that they arise from it and are parts thereof, although they do not grow to the partition. Again they are vnited a good way in their sides to the forehead bone: on the inside they are so conioyned with the third bone of the iaw, that *Falopius* hath referred this third bone of the iaw to the addiments of the Syue-bone and that not without good reason. In these the ayre which is drawne in together with odours receiues an alteration. They are vnequall and rough, that the excrement of the Nose should not perpetually distill downe, and in the French disease they are easily gnawne asunder.

Below at the pallat, the fourth bone of the iaw [tab. 7, fig. 9, A] and the sixt [tab. 8, fig. 9, II] together with his fellow do make the greatest part of the capacity of the nostrils where they open backward into the Chops.

A briebe of
the bones of
the Nose.

In a word, this whole bony cavity of the nostrils is formed of bones both on the inside and on the outside. Without, either before or at the sides, outwardly and before, aboue by the fourth [tab. 8, fig. 8 B] and fift [≡] bones of the vpper iaw to which gristles are adioyned. Below at the pallat, by the fift [tab. 8, fig. 9, A] and the sixt. [II] On the inside by the spongy bone of the head, [tab. 9, fig. 10, K] by the two spongy bones of the nostrils, and by the partition of the nostrils: [O] at the sides the cavity is made vp by the second, [tab. 8, fig. 8, Δ] the third [○] and the fourth [from X to B] bones of the vpper iaw.

Of the Yoake-bone.

The yoake-
bone.

The Yoake-bone [tab. 7, fig. 6, X] is called *ζυγωμα*, because it is made of two bones ioyned together. It is seated in the sides of the face vnder the orbe of the eye. This is no peculiar bone though it haue a peculiar name, but is compounded of two processe of two seuerall bones: one of the Temple bone another of the first bone of the vpper iaw, which two processe are in the middest ioyned together by an oblique suture [tab. 7, fig. 6 Y tab. 8, fig. 8 P] and so make one bone like a yoke, although me thinks it is better compared to a bridge. On the outside it is gibbous, within hollow. The roots on either side are thicke, But the middle of the processe which issueth out of the Temple-bone is but slender.

His substance.

The substance of it is hard and almost solid, almost lsay, for it hath a cavity in it, such as it is, wherein it containeth marrow for his nourishment, yet is it somewhat solid too, the better to defend the Temporall muscle, especially his Tendon (before which it is placed) from outward iniuries: beside the muscle called *mansorius* taketh his originall therefrom, and againe it strengthneth the Scull which is there but thin. And finally saith *Platerus* and with him *Laurentius*, it giueth a great strength vnto the orb of the eye which swelleth out a little aboue it. And so much of the yoake-bone: now we proceed vnto the vpper iaw.

CHAP. IX.

Of the Sutures and Seames of the upper iaw.

THE iaw is called by *Aristotle* *σινγών*, because when we hold our Iaws together we keepe silence, which the Grecians call *σινγών*; it is also called *γένυς*, because there the beard doth first flourish or breake out. The iaw is double, the vpper and the lower, called by *Hippocrates* and *Galen* *άνω*, and *κάτω γένυς*.

The diuision
of the face.

The vpper iaw is the bony part of the Face, which maketh the lower part of the orbe of the Eye and the sides, the cavity of the Nostrils, the Cheeks, the Pallat, and containeth the vpper rowes of the Teeth.

This vpper iaw is to be considered either whole or according to his parts of which he is compounded. In the whole iaw we consider his conformation and his connexion which is made by sutures. In the consideration of the parts we will examine the bones whereof it is compounded.

The protuber-
rations of the
vpper iaw.

The conformation of the whole iaw is diuers, broad aboue and narrow below, because of the protuberations, perforations and cavities which are therein. The prominences or protuberations are aboue in the middle of the face where the nose is formed, [ta. 8, fig. 8 f] which is peculiar only to man, for onely a mans Nose swelleth out or standeth off from his Face. At the sides it swelleth on both hands, at the Temples to make the lower edge or verge of the Eyes and of the Cheekes [ta. 8, fig. 8 aboue r] although it also make the lower cavity of the eyes.

yes. Below on the outside, where the roots of the teeth are it buncheth circularly: [under A] within it maketh the anterior and greater part of the pallat which is rough, [ta. 8 fig. 9, 17] and in the circumference it protuberateth for the dens or sockets of the teeth. [fig. 9 iii]

The perforations.

The perforations are partly small, through which the veines, arteries, and nerves are transmitted, as shall be said in the History of the particular Bones: partly great, two in the lower cavity of the eyes, as in the second bone [fig. 8. C] through which the rheume falleth and a small Nerue vnto the nostrils; and in the fourth through which a little nerue runneth to the outside of the cheekes. So also in the foreside of the Palate and in the middest thereof one perforation which admitteth a small veine and a little Artery [fig. 9, 2] and on the backside of the palate two on either hand which run vnto the sides of the nostrils. [at V]

The cavities.

The Cavities are Proper and Common. Proper to the fourth bone wherein there is a den closed vp within the bone at the sides of the nostrils [fig. 8, vnder BV] and the sockets made to receiue the teeth, of which we shall speake in the descriptions of the fourth bone. The Common cavity is that of the nostrils, distinguished by the partition and filled about with the spongy bones, which cavity both outwardly in the nose [fig. 8 00] and inwardly in the mouth [fig. 9, at qq] is alwaies open, that the ayre in expiration may retorne backward, and in smelling be drawne vpward, and Rheume be that way euacuated.

This vpper iaw in all creatures is immoueable excepting the water Crocodile, of which saith *Archangelus*, there can be no particular reason giuen. A common Reason he giueth out of *Aristotle* where he saith, that the Body is the Instrument of the Soule, and therefore Nature hath accommodated the Body and so furnished it (as we see) for the behoofe of the Soule in Men, in Oxen, Horses, yea and in the Crocodile too, whose soule hath some power or faculty to vs vnknown, but expressed by the motion of the vpper iaw; but his neather iaw is so vnted with the Temple-bones that it cannot at all be moued, because it is fastned into 2 bosomes, whereas the vpper is articulated on either side with a broad head. Yet *Aristotle* saith, that his vpper iaw was made moueable to recompence the defect of his feete, because they are little, and vnfit either to catch or to retaine his prey.

Why the Crocodiles vpper iaw is immoueable.

In a Parrot or Poppingey both iaws are moueable, and he moueth them either one at once or both together as he listeth. In a man the vpper iaw is immoueable, first, because the motion thereof would haue hindred his sight. Againe, in receiuing of Odours and inspiration of aire the motion of the vpper iaw would haue made an interruption. Thirdly, hard meats could not haue bene so well broken; for as in a Mill where Corne is ground one stone must rest immoueable the other must run vpon it, so in the grinding or breaking of meate it was necessary that one part which is the vpper iaw should be immoueable, the other which is the lower iaw moueable.

Why a mans iaw is immoueable.

Heereto we may adde, that the immobility of the vpper iaw is a beauty to the face, for if it had bene moued then it must necessarily haue bene corrugated or contracted, and so the elegancy and forme of the face bene deformed, whereas in the frame of mans body our Wise Creator had an especiall respect to make the face beautifull, because it is the image of the soule; wherefore a mans face is not set off from his head as in brute beasts, but made short and round for beauty and better forme.

The vpper iaw is fastned either with the bones that are about it, or with the proper bones of which it is compounded; which connexion is made by immoueable commisure or coniunction, and that partly by sutures or seames, partly by *Harmony* or *Cementation*. Of these Sutures or commisures some are common vnto the skull with the bones of the vpper iaw, and those are five, of which we spake before in the fift chapt. Others are proper to the bones of the iaw and are nine in number, and ioyne together twelue bones of the iaw; some of these, that is, two, are in the cavity of the nostrils, the other seuen are on the outside. Againe of these seuen five are common to two bones of the iaw ioyning together, and two are peculiar to one bone. Of these in order.

Connexion.

The first internall suture we meeete withall in the cavity of the nostrils, and it is common to the partition and the fift bone. His course is short and obliquely downward. [table 8, fig. 8, vnder f] The second is also found thereabout and is common to the partition of the nostrils and the fourth and sixt bones of the iaw, his course is somewhat longer and forward, but ouerthwart [tab. 8, fig. 8 g].

The first internall suture.

The first externall suture runneth obliquely to the cheek-bone, and of it there are three parts, the first runneth through the cavities of the Temple-bones outward and downward to the lower side of the cheek: the second through the foreside of the cheek vpward and inward

The first externall.

inward to the middle part of the eye. [tab. 8, fig. 8 from *a* unto the lower *D*] The third in the cavity of the eye; it runneth backward and outward [From the lower *D* to *Q*] and determineth at the second suture which is common also to the scull. This first externall suture is common to the first bone and the fourth.

The second externall suture runneth circularly in the orbe of the eye about the compasse of his bone; it beginneth at the third common suture and runneth downward, then presently forward, and againe from thence vpperward. This suture is common to the second bone with the third on the backside, and to the fourth bone on the outward and lower side. [tab. 8, fig. 8 from *V* to *i*. from thence to *C* and *Δ*]

The third is also in the orbe of the eye, and runneth directly outward from that suture which is called the second common suture of the wedgebone, and determineth in the second suture; it is common to the third and fourth bone. [tab. 6, fig. 8 from *d* to *c*]

The fourth is at the outside of the nostrils, and runneth from the third common suture directly downward throughout the length of the fift bone as far as to the gristle, and this is common to the fourth bone and the fift. [tab. 8, fig. 8 from *z* to *e*]

The fift is in the pallat and runneth ouerthwart through the backside thereof, and it is common to the fourth bone with the sixt. [tab. 8, fig. 9, *t u*]

The sixt is in the vpper part of the nose, and runneth from the middle of the Browes, where the third common suture is, directly throughout the length of the nose, and distinguisheth the fift bone through the middest.

The seventh is in the pallat, a line rather then a suture: so also is the sixt saith *Columbus*, it runneth directly through the whole length of the Pallat, and is very conspicuous both within and without the Nostrils, and diuideth thorough the middest the fourth bone and the sixt. [table 8, fig. 9, *y e*] So also in the forepart of the iaw it runneth from the cavity through the middest of the shearing-teeth directly downeward vnto the pallat, [table 8, figure 8, *b*] but in Dogges, Apes, and Swine, and those creatures whose Dog-teeth are strong and hand ouer the iaw, we meete, saith *Vesalius*, with two sutures or Harmonies which are not to be found in a man, and therefore they haue peculiar bones in which the Shearing-teeth are fastned.

The bastard
Sutures.

There are also certaine Bastard Sutures which do not quite diuide the Bone but are rather lines or inscriptions and are onely found in the fourth bone: first in the lower part of the orbe of the eye which runneth from the first perforation obliquely vnto the compasse of the eye but no further, and diuideth the fourth bone betwene the vpper seate of the first perforation and the circumference of the eye. [table 8, figure 8, *i*] Again, in the forepart of the palat runneth a line obliquely from the second perforation of the fourth bone vnto the Dog-teeth.

Disagreement
betwixt *Falopius*
and *Col.*

This saith *Columbus* in children is very manifest, but in growne bodies there remaineth no signe or footstep thereof. Heereto opposeth *Falopius* in his Observations where he saith, I dissent from them who say there is a suture found attaining ouerthwart vnder the pallat to the Dog-teeth on either side, which in children should be conspicuous, but in growne bodies is obliterated. For I finde, saith he, that this is a diuision or a rift rather then a suture, because it doth not separate one bone from another nor appeare on the outside: for how can it be a kind of articulation if it do not ioyne one bone with another. Moreover, I cannot be perswaded that this diuision, such as it is, is more conspicuous in children then in growne bodies, for I finde it very seldome obliterated and that in very old men. Thus farre *Falopius* & *Baubine* addeth, that although in men it doe not diuide the Bone throughout, yet in Dogs, Apes and Hogs it doth, in which creatures it doth not onely diuide the fourth bone in the pallat, but also on the outside in the forepart of the iaw.

CHAP. X.

Of the Bones of the vpper Iaw.

THE vpper iaw doth not consist of one Bone but of many, not onely to make it fitter to repell iniuries, but also and especially that out of their Commissures and coniunctions might issue Ligaments to make vp the construction or frame of the Muscles, which by that meanes are more firmly fastned to their originals as to bony

bony parts and thereby made the stronger. Beside, it was not fit that the vpper Iaw should be on euery side a like thicke or hard, or fast or soft. The bones therefore of the vpper iaw are of two sorts. Common and Proper.

The Common Bones are the Wedge and Spongy bones called also the seauenth and the eight bones of the head. From this eight bone doe yssue two spongy Bones seated in the inside of the nose, which distinguish the vpper part into two sides, to these are ioyned other two which make vp the inner orbe of the eye, which also we will account, as other men doe, for the third bone of the Iaw. But of these wee haue partly spoken before in the seauenth chapter among the bones of the Head, partly in the eight amongst the bones of the Nose, and therefore we will come now vnto the proper bones of the Iaw.

The common
Bones of the
Iaw.

The proper bones of the iaw which helpe to make the face are twelue. The first [ta. 8, fig. 8, r] maketh a good part of the Cheeke, the lower part of the eye towards the Temples, that round extuberation which Hippocrates caeth *κυκλον προσωπου*, the circle of the countenance, one part of the yoke-bone, a little of the temples and the vtter angle of the eye. The figure of it saith Columbus is diuers: Bauhine saith it is triangular, sending fourth of a broad middle, thre protuberations; one to the angle of the eye, another to the teeth, and a third which is most notable, that is, the proesse which maketh a part of the yoke-bone, [ta. 8, fig. 9, r with r] and hauing a perforation or two but very small ones.

The proper
Bones: first.

This first bone is ioyned to foure bones: aboue, to the forehead bone where the eye-browes end by the first [ta. 7, fi. 6, and 7 g] common suture: [ta. 8, fi. 8 R] behind, to the wedge-bone by the second common suture: [ta. 8, fig. 8, from S to Q] at the sides, it is ioyned by his proesse to the proesse of the Temple bones by the fourth common Oblique suture: [ta. 8, fig. 8 P] below, to the fourth Bone of the vpper iaw neere the cheeke, and in the lower part of the orbe of the eye. [tab. 8, fig. 8 from the lower D by the vpper D vnto Q]

The second bone [tab. 8, fig. 8, A] standeth in the great angle of the eye neere the Nose, and iust at the beginning of the angle where the holes goe into the nostrils [ta. 8, fig. 8, C] wee meete also with a caruncle which like a glandule receiue the Phlegme which floweth from the Braine vnto the eye to deriue it vnto the nostrils that it should not fall downe the cheekes. Galen also addeth, that Medicines which are put into the eyes, do vse to issue out of the nostrils, whereat Columbus much marvelled, because such medicines must penetrate the Membrane before they can get into the nose.

Second.

This is a small bone, thin as a scale and transparant, and because it hangeth but loosely, as being rather ioyned by harmony then by suture to the outside of the fourth bone, it is easily broken and lost, and therefore we rarely meete with it in the skulls digged out of the earth, for being in a moist place it easily putrifieth; but in those skulls that are boiled it is easily preserved. It is ioyned to three bones: aboue, to the forehead bone by the third common suture: [ta. 8, fi. 8, neere V] behind, to the third bone of the iaw by the second external suture; [from V to V] before & below to the fourth of the iaw by the same suture; [from C toward X] sometimes also it is ioyned vnto the spongy-bones of the Nose. And this is the place where those Apostemations are which the Græcians call *αἱματωπας*, which if they be neglected doe penetrate to the mouth, and do end into weeping *Fistulaes*. This bone also hath some perforations; aboue some small ones which are common, one also very notable which is common to it with the fourth bone. [tab. 8, fig. 8, C] which runneth out of the inner angle of the eye directly downward into the cavity of the Nostrils; the vse of it is to transmit a small portion of the lesser roote, commonly so called, of the third coniugation, and also Rheume or Phlegme.

Aegilops

Weeping Fi-
stulaes.

The third Bone which we said was the fourth part of the Spongy-bone, [tab. 8, fig. 8, B] but is by most made the third of the vpper iaw, is seated in the inner side of the eye, and within is continuall with the fungous bones of the Nostrils. This is broader then the second quadrangular but somewhat round, thin and transparant like the scale of a fish; without smooth, within rugged and vnequall, because of the scales that cleave vnto it: and if you breake it, within you shall finde large cavities filled with ayre.

Third.

It is ioyned to foure bones. Aboue to the forehead bone by the third common suture, and there is a good length off the suture betweene them. [table 8, fig. 8 from T toward S] Behind, to the wedge-bone by the same suture, but the length of it is lesser. Before, with the second Bone of the iaw by the second suture. [from V to C] Below, to the fourth bone of the iaw by the third suture. [from C to b]

The fourth bone [tab. 8, fig. 6, A A] maketh for the most part the forepart of the nostrils and

The fourth.

and of the mouth, into which all the vpper Teeth are infixed, also the sides and lower part of the pallat and of the holes of the nostrils: yea and beside the lower part of the orbe of the eye toward the Nose. *Galen* calleth it *Os male* the Cheek-bone, and he saith it deserveth well to be called by the name of the whole, the vpper Jaw. It is much larger then any other of the bones, and is circumscribed with many sutures, for it abuteth vpon seuentene bones if you reckon the Teeth. Aboue neare the Nose it is ioyned to the forehead bone (yet but a little way) by the third common future. [*tab. 8, fig. 8, X R*] Below to the wedge bone by the second common future [*ta. 8, fig. 8, from D to H fig. 9, from d to e*] where also the vpper part of the wedge-bone and the iaw do yawne into the orbe of the Eye.

His connexions.

It is also ioyned with other bones of the vpper iaw: as to the first by the first oblique future [*tab. 7, fig. 6, ab Q*] in the Cheeke, the orbe of the Eye and the cauities of the Temples. Before to the second in the inner angle of the eye by the second future. [*ta. 8, fig. 8, from C toward X*] Behinde to the third by the third future. [*from b to c*] On the outside to the fifth bone in the top of the Nose by the fourth future: [*e r*] to the sixth in the Pallat by the fifth future: [*ta. 8, fig. 9, tu*] and finally to his owne companion by the seventh future, or rather by a line, partly in the forepart of the iaw [*tab. 8, fig. 8, b*] where the furrow is of the vpper Lip, partly in the pallat. [*ta. 8, fig. 9, x y*] Into this fourth bone also are the vpper Teeth fastened by *Gomphosis* or way of *Mortize*, and finally it is vnited vnto the Gristles of the Nose.

Perforations.

It hath also perforations and dens. The perforations are Common and Proper: one Common which is very small toward the inner angle of the Eye. The proper are 3. two in the lower part of the Eye, on each side one, which is onely couered with a bony scale, and runneth from the lower part of the Eye outward: his vse is to transmit a surcle of the lesser roote, commonly so called, of the third coniugation of sinewes out of the orbe of the eye into the Face. [*tab. 8, fig. 8, at b*]

The third hole is in the Pallat at the backpart of the *Shearing* or shredding Teeth, where both bones of the iaw do meete. [*tab. 8, fig. 9, z*] It runneth out of the Pallat into the capacity of the Nostrils, and transmitteth a small veine and a small artery vnto the nose; and at the sides hereof there appeareth a future in young children.

Cavity.

The dens or cauities of this fourth bone are of two sorts: of the first is one on each side at the lower sides of the cavity of the nostrils vnder the orbe of the Eye. It is a great cavity, and so large sometimes that in it a man may lay his thumbs end: and therefore it may well be likened to those hollow images made of molten waxe; yet it is couered with an attenuated bone, blowne vp as it were round, [*tab. 8, fig. 8, vnder B A*] which was made partly because of the lenity of the bones, which in this place stood in neede to be thicke by reason of the situation of the eyes, partly because it is most fit to forme the voyce, so saith *Vesalius*.

This cavity is not to be found in young children, but is made as they grow, and is inuested with a very fine coate, it is also found full of mucous or slimy phlegme, or marrow saith *Archangelus*, whereby the bones that containe the Teeth and all the vpper Teeth also are nourished. Of the second kinde of dens of this fourth bone, are the sockets or mortizes of the Teeth which are insculped in the lower brinke thereof, in which the teeth are fastned. [*tab. 8, fig. 8, vnder b.*]

The fifth.

The fifth bone of the vpper iaw, [*ta. 8, fig. 8, z z*] which with his companion maketh the bony prominence of the Nose, is a small bone and almost quadrangular, but somewhat long, yet shorter by farre in a man then either in Dogges or in Apes. It is a hard, solid, broad and thin bone having small common perforations in it. It is ioyned aboue to the forehead bone by the third common future: [*tab. 8, fig. 8, y z*] againe in the sides to the first bone of the iaw on either hand, and outward to the fourth bone by the third proper future, [*fig. 8, from c to r*] and in the middle it is ioyned to his companion by the sixth future [*fig. 8, from z to f*] which is not much vnlike a harmony, and runneth directly from the future of the forehead throughout the length of the bones of the Nose. Below it hath no future but is rough and vnequall that the gristles of the Nose might take better hold vpon it. On the inside where these two bones are ioyned, they adhere to the bony partition vnder them, and that cleaueth to the spongy bone.

The sixth.

The sixth and last bone of the vpper iaw (for you must reckon every one of these double, one on one side, another on another) [*tab. 8, fig. 9, n*] is placed at the end of the pallat, where the nostrils do determine into the chops and maketh together with his companion the backpart of the circumference of the nostrils and the pallat. It is a broad bone thin and solid, and in the end where it is rough it resembleth a semi-circle. [*tab. 8, fig. 9, aboue q*] It is ioyned

ioyned behinde, to the wedge-bone at his wingy processe: belowe, and on the outside by a part [q] of the second common suture. On the inside to the partition of the nostrils by the second externall suture: [tab. 8, fig. 8 g] againe, to the fourth Bone of the iaw by the first transuerse suture; [fig. 9, f] and finally, to his companion in the backe-part in the pallat by the sixt suture running along the length of the pallat [tab. 8, fig. 9, from t to x]

It hath two perforations on either side, one large which runneth vpward and backward to the ninth common hole of the wedge-bone, [tab. 8, fig. 9, a little below u] the other small, which sometime determineth into the former, sometime into the second common suture. [aboue q at r]

The perforations.

CHAP. XI.

Of the lower Iaw.

The lower Iaw, which the interpreter of *Hallabba* calleth *Faucem* [table, II, figure 1, and 2] maketh the lower part of the capacity of the mouth, into it the Teeth are infixed and it is articulated to the scull. In men it is moueable and by it they chew their meate: for because the Teeth must grind and cut that which is eaten, it was necessary that the vpper Teeth should depart from the lower and returne againe vnto them. And because in the descent it needed no strength, but in the ascent very great strength, as well to lift vp the weight of the Bone as to breake the meate, therefore it is depressed by weake muscles, but lifted vp by exceeding strong, as we haue shewed before in the 10 Booke. This Iaw in a man is shorter then in any other creature proportionably. It is almost orbicular because of the roundnesse of his face wherein is his beauty. In other creatures, saith *Galen* (excepting an Ape, whose face and hands are much like vnto a mans) the Iaws are long and prominent, because they vse them instead of hands, and because they were to be enclined to the earth to gather their food.

The lower Iaw.

The figure of it is like a bow, the belly hollow for lightnesse, and that it might not offend the muscles which moue it. Before, in the top of the chin it is broad and thicke, in other creatures it is narrow and prominent. Behinde it is parted, partly that the passage of the meate should not be hindred, partly that it might more commodiously for motion be articulated to the scull on either side.

His figure.

For it hath on the backside on either hand two processe (some call them Hornes) which run vpward. One turned backward, [ta. II, fi. 1 and 2 C] broad and thin, ending into a cone or point called *κορυμή*, which receiue the tendon of the temporall Muscle; for that tendon compasseth it round about, and is very strongly implanted thereinto; and hence haply it was, that *Hippocrates* saith, the luxation of the lower iaw, is most what mortall, because of the distention and alteration of the temporal muscle. A disease common in the *Bermudas*, of which they dye within 2 or 3 dayes.

Processe.

The other and the backer processe is called *κορυμβότης*, and is like a knot. It runneth backward, hauing a long prominent head and transuerse, [fig. 1, and 2 A] whereunder there is a notable necke. [B] By this head it is articulated into a cavity on either side answerable there-to insculped in the Temple-bone, which articulation is made betwixt the roote of the yoake-bone and the Hole of Hearing. By this articulation the iaw is moued vpward to the scull, downward also and somewhat to the sides: ouer the head, as also ouer the sinus there is a gristle couering them like a crust.

But besides this which is common to all ioynts, there is another gristle reposed betwixt the bosome and the head which is smooth, thin and soft, doing not onely the office of a Ligament to containe the processe within his cavity, but also it maketh the motion of the ioynt more glibbe and slipping. Moreouer, together with the other gristles in the strong and perpetuall motions of the iaw it keepeth the bones from breaking, at least from wearing one against another.

This ioynt also of the lower iaw with the Temple-bones is covered with a common Membranous Ligament. On the backside on either hand where it shooteth out his processe [figure 1 and 2 EE] it is exasperated with small protuberations like little rising hillocks especially where it is broadest behinde and below. Before and on the inside in the middle of the chin there riseth a bunch vp, [figure 2 H] made for the stronger insertion of the pro-

- E. The Cavity that is in the grinding teeth when they are broken.

TABVLA XI.

per muscles by which it is led downward, as also to giue a more commodious originall to some muscles of the tongue; for where the place is rough and vnequall there the muscles will cleaue the faster. In like manner also is it exasperated on the outside at the top of the chin; [tab. II, fig. 1 vnder G] that the Muscles of the lower lippe might better arise therefrom.

The bosomes.

At the sides of the processes it hath superficially or shallow bosomes, yet so that it is more hollowed on the inside then on the outside. Without on each side one, and that large; [fig. 1, betwixt BC] within two distinguished by a certaine knot, [fig. 2, neere DB] The anterior at the roots of the teeth was made to giue way to the gummes, the posterior and the larger affordeth a seate vnto the muscle that *lurketh in the mouth*, that his thicknesse and bulke should not fill vp the narrownesse of the chops.

The composition of it.

It is compounded of two bones, for in infants the two bones are very manifest, ioyned together in the middle of the chin by a plentifull gristle, so that in some bodies at seuen yeares of age, the markes or footsteps thereof doe remaine, but in growne bodies the gristle is changed into the nature of a bone, and those two bones are so strictly vnited, that there doth not appeare so much as any shew of a line betwixt them, neither can they be separated by boyling, by putrifaction, or by any strength, which is the reason why *Vesalius* concludeth it to be but one bone. For, saith he, although in young children it be formed of two bones vnited together, yet we cannot simply say that the lower iaw consisteth of two bones, vnlesse we will also say, that the Nowle-bone, the *vertebra* or rack-bones and the bones that are ioyned vnto the sides of the Holy-bone be made of many bones, for in children euen these are built vp of many bones.

Vesalius.

Falopius

Falopius makes answer, if *Vesalius* say we may not make denomination from imperfect partes, then certainly all Anatomistes haue erred who speake so much of Appendances: for they are found onely in imperfect bones, not after the body is growne: but to proceed.

The Line which we see in the iaw of a childe is in stead of a future, that out of it the Ligaments might be produced which go into the muscles of that place. In Dogs, Oxen, Asses, and many other creatures, these two bones may easily be parted without coction or any great violence.

The bone of the lower iaw is very hard, and for the most part solid to make it the stronger; not because it alone was moueable, but because it was to endure diuers and those very violent motions in biting and chewing; within it is excauated that the weight thereof should not be offensive or hinder the muscles that moue it.

It hath also cavities to containe the marrow which is his nourishment, which are not exculped or grauen in the backpart of the iaw as in brute beasts, but more forward toward the Region of the Chin and the sides of the iaw vnto the sockets of the teeth, and therefore about these places it is thicker, as it is thinner toward the backpart.

That the lower iaw is made thicker by reason of the teeth that wereto be fastned therein hence it appeareth, because in old bodies and those who haue lost their Teeth, or where the sockets of the teeth are grown vp; in such bodies I say the iaw groweth much thinner and narrower from below vpward. These sockets, or beds, or mortize holes, or what you list to call them, wherein the Teeth are infixed, are engrauen in the embowed compasse of the iaw.

Perforations also it hath on either side two, which runne through the iaw like a Canale or pipe; for put a bristle into the hole of a iaw when it is drye on the inside, and you shall easily thrust it through the hole on the outside, and if you breake the iaw in sunder you shall finde that the way betwixt the outward and inward hole is continuall and formed round like a canale. The one of these perforations is inner and backer at the internall bosome not farre from the proccesses.

It is on each side one, and greater then the other, vnequall also or rough, beginning like a scale, [tab. 11, fig. 2, F] and through it a portion of the third coniugation of nerues is disperfed vnto the roots of the Teeth (together with a small veine and artery) which sendeth small surcles to the teeth and to the iaw.

The other perforation is small and round, grauen or thrilled without at the sides of the chin, [tab. 11, fig. 1, at G on either side] and by it the forehead nerues being now within, doe againe returne out of the iaw outward into the lower lip, and this second perforation is far lesser then the first.

CHAP. XII.
Of the Sockets of the Teeth.

IN the circumference or margent of both the Iaws, which place *Galen* called *Odontidia*, we meete with certaine cavities or hollow places which, the Latines call *Alueoli* or *Locelli*. They are digged deepe that the teeth like so may nayles might be firmler fastned in them by *Gomphosis* or by way of Mortize; and therefore the roots of the teeth are made iust fit and answerable to the holes of the law, for if they had bin broader the composition would haue been too dissolute, and if they had bin too narrow the roots of the teeth would not haue attained to their bottomes, but being fit as they are, they are very firmly contained. The number of these sockets can hardly be assigned, because they are sometimes single, sometimes double, sometime treble, according to the variety of the roots of the Teeth.

Morcouer, although they be bony, yet they appeare to be almost like wax, and may well be compared to the holes of a hony combe which are often obliterated and often againe renewed: for when a Tooth is drawne, vnlesse a new one grow vp, the hole is so constringed that there remaineth no print thereof: yea if a Tooth fall out and a new one doe rise vp in his roome, the former socket is obliterated and a new one grauen for the new Tooth.

Hence *Falopius* concludeth, that the liuely and quickning Formative faculty remaineth in the Teeth vnto the period of a mans life, for by it they encrease and receiue their forme. So in the Cheekes and the Iaw when those Teeth which we call *Genuini dentes* or *dentes sapientia* doe shoote out, haply about seuentie yeares of age, yet euen then new

Cavities.

Perforations.

The Sockets of the Teeth.

The formative faculty remaines in the Teeth.

sockets are made for them. Againe, at fourescore when the teeth fall, the sockets grow vp and the iaw in that part is so compressed that the bone on euery side cleaueth together, and at length is vnited. For the sockets are not only filled with a bony substance and rammed vp, but each partition growing to other doe make a sharpe edge which in old men serueth in stead of teeth, if not to cut, yet somewhat to breake and chew their meat. And so much of the Sockets, now we come to the teeth themselves.

CHAP. XIII.

Of the name, definition, figure, magnitude, number, site and articulation of the Teeth.

The names.

He teeth are called in Greeke, *odon*, as it were *odon* of *edon*, which signifieth to eat. In like manner the Latines call them *Dentes quasi edentes* of eating. They are the hardest of all the bones, hollow within, having small veines, arteries, and nerues: articulated to the sockets or dens of their owne law, *Per Gomphosin*, or by way of mortize, fastned with membranes, and fl sh, or ligaments, and primarily created for the comminution or mitigation or chewing of the meate.

Arguments that teeth are not bones.

That they are bones some men doe deny, first, because bones are insensible, the teeth sensible. Secondly, because bones haue certaine limits of auction or increase, neither doe they euer grow againe if they perish, but in teeth it is quite contrary. Thirdly, because they are harder then other bones. Fourthly, because bones exposed to the ayre, doe grow blacke, whereas the teeth keepe their whitenesse. Fifthly, they say, that *Hippocrates* in the eighteenth Aphorisme of the first section distinguisheth them from bones, where he saith, that cold things are enemies to the teeth, to the bones, and to the nerues. Finally, say they, there is a stone that will consume flesh called therefore *Sarcophagus*, which within forty dayes will deuour the whole body except the teeth. If therefore the teeth were of the nature of Bones, they also would be consumed.

Answered.

We answer to the first, that sense is not of the Nature of a bone. To the second, that they grow, because in attrition they are worne. To the third, that *more or lesse* doe not change the species or kind, otherwise the spongy Bones should be no bones. To the fourth, that they are accustomed to the outward aer, and haue no periostion on them, and the Philosopher saith, that that which is accustomed maketh no impression or alteration. To the fifth, that is, to *Hippocrates* authority we say, that the bones & the teeth are affected by cold diuersly, the bones onely by suffering, the teeth not onely by suffering but also by sensation. To the sixth, first we may safely doubt of the experience; secondly, we may say that the teeth are not consumed, because they are harder then other bones.

It remaineth therefore according to *Hippocrates*, *Aristotle*, and *Galen*, that the teeth are bones, for saith *Galen* they cannot be referred to any other similar part, and therefore he placeth the teeth vnder the common *Genus* of the bones, and the rather because the qualities of their matter doe agree, as hardnesse, solidity, smoothnesse, whitenesse, &c. yet there are some differences betwixt them and other bones. For among all the bones none but these haue any exquisite sense, because the teeth alone doe admit nerues into their cavity.

The teeth alone doe increase as the life increaseth, that without any detriment they might performe their Offices: for being worne in the chewing of meates they are increased againe, but onely so much as they are worne away, otherwise they would soone faile. The other bones haue no sense or but obscure, neither doe they increase alwayes, but when they come vnto their state or perfection they make a stay, because they are not changed in the performance of their functions.

How they differ from bones.

They differ also from other bones, because they are naked, hauing no periostion vpon them, for then they would be payned in the wearing; hence it was that *Aristotle* doth oftentimes, not number the teeth among the bones, but sometimes saith they are bony, sometimes that they resemble the nature of bones. And truely in their hardnesse, fastnesse, or solidity they doe exceed other bones, yea, they are little softer then stones themselves, if they bee not all out so hard, especially about their extremities. Some are stony like a millstone, others are sharpe like the steeld edge of a knife. They were made very hard that they might not weare so soone, or bee broken in the chawing or breaking of hard things, for they are not lined either with fatte, or gristles, as other ioynts are to hinder attrition. The Teeth therefore doe breake bones, resist the edge of Steele, neither can they easily, as other parts

Why they are hard and how.

of

of the body be burnt with fire. *Hippocrates* in his booke *de Cornibus* ascribeth the cause of their hardnesse to the quality of the matter out of which they are ingendered, for he writeth that out of the bones of the head and iaws there is an increase of a glutinous matter. In that glutinous matter the fatty part falleth downe into the sockets of the gums where it is dried and burnt with the heate, and so the teeth are made harder then other bones because there is no cold remaining in them.

Their outward surface is by nature white, smooth and polished, but in age for want of cate Their surface. or by disease they become liuid or dusky. There groweth also vnto them a hard scaly matter by which as also by corruption they become rugged and vnequall, yet saith the Philosopher a horses teeth become whither as he becomes older.

Their forme is before somewhat round, behind more plaine; where they are ioyned one to another they are euen, and in their extremities sometimes thin, sometimes sharpe, sometimes plaine, but alwayes vnequall. Forme.

They differ among themselves in figure, magnitude, and number. Their figure in man differeth according to the difference of their vse in chewing. In fishes they are only acute or sharpe. In those creatures that chew the cudde they are of a double forme; some *Grinders* and some *Shearers*. In men according to the three speciall diuisions of meates there are three kinds of teeth, *Shreaders* or *Shearers* called *Incisores*, *Dog-teeth* called *Canini*, and *Grinders* called *Molares*. Difference.

Againe mans teeth do not stand out of their formes as a Boares tuske, but are concluded or shut within the mouth; neither are they set like the teeth of a Saw as it is in dogs, for their teeth are giuen them in stead of weapons.

The teeth of a men are much lesse then the teeth of many other creature lesse then he, for his mouth is much lesse; for according to the magnitude of the mouth is the strength of the teeth which consisteth in their figure, hardnesse, and quantity; yea mens teeth compared among themselves are not equall but some greater some lesser, for the grinding teeth are greater then the rest. Magnitude.

The number of the teeth is not in all men one and the same, for some haue more, some haue fewer, yet the more the better, for such, saith *Hippocrates* in the sixt section of the second *Epidemion*, are long liued, where as those that haue few teeth are but short liued as *Aristotle* saith in the 3 chapter of his 2 booke, *de historia Animalium*. The reason is, because the paucity and rarity of the teeth is an argument either of the want of spermatie matter or of the weaknesse of the formative faculty. Number.

Againe, those that haue but few teeth do not chew their meate so throughly, nor prepare it so well for the stomacke. So that the Chylus is not so well concocted, and by consequence the bloud not so pure; for the second concoction which is in the Veynes of the Liuer doth not amend the error of the first concoction which is made in the stomacke. Stories make mention of some men who haue had but one tooth in their vpper iaw, and therevpon haue some been cald *μονοδοντες*, as *Euripheus* the *Cyrenian*, *Euripolimus* of *Cyprus* and *Pirrhus* the King of the *Epirots*. Some in stead of teeth haue one continuall bone, such was the Sonne of *Prusias* King of the *Bythinians*. Some haue had a double row of Teeth, as *Dripetimus* the Sonne of King *Mithridates*, *Trimarchus* of *Cyprus*. Some haue had 3 rowes as *Hercules*, for so *Caelius Rhodiginus* reporteth in the third chapter of his fourth booke. But for the most part there is but one row which is called *οεσχυς*, *Septum* the hedge, because it hedgerh in the tongue. In both iaws there are in growne bodies 32 Teeth, 16 in each iaw, in some men 30, sixteen in the vpper iaw and 14 in the neather; in some 28, which is the least number, and then the foure last are wanting, for they doe not breake out in all men nor at the same time, sometime lying imperfect within their sockets, sometimes not formed at all by Nature. Diuers rowes of teeth in some men.

And truly the grinding Teeth are the cause why Authors doe not agree in the number of the teeth, for the number of these *Grinders* is often changed, the *Shearers* and the *Dog-teeth* in man vary seldome. These Grinders are sometimes five in a side, sometimes foure, sometimes foure on the left hand, and five on the right, or on the contrary; or else foure below and five above, which variety is made by those Teeth which we call *Gennini*. The Teeth were made many not one, that they might do seuerall offices in cutting, breaking and chewing the meat; againe, that when one is pained or perished either by force or by corruption, the affection should not become common to them all. Why many teeth.

A mans Teeth are set in both parts of his mouth in the vtter compasse of both the iawes;

Fishes have their Teeth in their Pallate and their tongue : Crabs and Lobstars in their stomacke, where they are called the Lady.

Alexander Benedictus witnesseth that in a mans pallat sometimes Teeth have been ingendered, and *Eustachius* testifieth the same thing from his owne experience in a woman of Rome. Those creatures that chew the Cud have their lower gang of Teeth whole, which reacheth euen to their Lippe, so disposed and so equally ranked, that saith *Galen*, Nature is much to be commended for so ordering the dance, so he calls their ranke or course.

Their order.

The Teeth therefore are streight, inclining to neither part; before are the *shearers*, called *Incisores*, next to them the Dog-teeth called *Canini*, and then follow the *Grinders* or the *Molares* which are the hindmost, yet so that they are all disioyned with a decent and conuenable distance, which the *Gracians* call *epurion*, for they are set close one to another, and touch at the top, least that which is chewed should remaine in the spaces betwixt them and there putrefie.

The roots of the Teeth doe enter into the holes or sockets of the iawes, to which they are so fitted, that a nayle sticketh not faster in a post then they do in their proper places, euery rooth being compassed with slender processe and cauities of the iaws which hold them fast that they fall not out or be shaken.

Their Composition.

Euery Tooth also saith *Galen* hath a nerue, and that nerue helps to establish it, for when the nerue is loosened with too much moysture, the Tooth becomes prominent and mouable : beside they are very strongly tyed by Ligaments which passe betwixt their roots and the bottome of their sockets. The Gummies also doe establish the teeth very much, fastning about them very exactly; and this *Commisura* of the Gums and the colligation of the iawes, *Rufus* calls *habena* or the bridle. In a word the Teeth are vnited by the interposition of nerues, membranes and flesh. The nerue is inserted into the cavity, and so the Teeth may be said to be ioyned by *Synneurosis*. The fibres of the membranes do cleaue to the roots of the Teeth : the flesh compasseth them about, which being eaten away, they either grow loose or fall out, and so they are ioyned by *Synsarcofis*.

Is by way of mortize.

Hence we may gather that the articulation of the teeth is by *Gomphosis* or by *mortize* which is a kind of coarticulation, and yet *Galen* doubteth hereof and saith, that their composition commeth neare to a Coalition : neare it may be, but indeed they are coarticulated, which may be proued, because when for want of nourishment they grow dry and begin to wither, then their coniunction is not so stedfast but loose and vncertaine, which hapneth also when the nerue vnder them is ouer moyst. Finally, their rootes are simple, double, treble and fourfould.

CHAP. XIII.

Of the Shearers and Dog-teeth.

3^d Kindes of teeth. Both in view and generati on. *Incisorijs*.

WE said before that according to the three kinds of diuisions of Meats, there are also in men three kinds of Teeth called *Incisorijs*, *Canini* and *Molares*. *Incisorijs* wee call the *shearers* or the *shreadors*; [*ta. 11. fi. 3, D 1, 2*] they are seated in the forepart of the iaw, and because they are the first, they are called by *Hippocrates* and *Aristotle* *πρόσθιοι, primores*.

They are sharpe edged like a knife and broad also, the better to deuide that that comes betwixt them, and are therefore called *πρῆτοι*. Sometimes they sheare a thing asunder as a paire of pinsons doth a wire, and that is when the lower teeth are vrged, not against the ends of the vpper, but higher toward their bodies. And because these Teeth in laughter are discovered, therefore the *Grecians* call them *γέλαιοι*.

Are foure.

These *Shearers* are for the most part foure, and those two that are next the *Dog-teeth* are lesse then the other, and shorter then the *Dog-teeth*. [*table 11, figure 2. character 2*] *Gorrenus* saith that some men in stead of these foure, either aboue or below haue onely two, but those so broad that they take vp the roome and performe the vse of foure. Some againe in stead of foure *shearers* haue sixe, eight, or more placed without any order, some of them being right, others crooking outward to the Lip, others inward into the mouth, which are so offensive both in chewing and in pronounciation, that we are constrained sometimes to draw them, sometimes burne them, sometimes to file them. *Bauhine* maketh mention of a Doctor of Diuinity, whose two fore-teeth in the lower iaw were double, for when the two vpper were almost consumed about the fortieth yeare of his age two other grewe vp within them. The part of these Teeth which standeth without the Gummies is narrower betwixt the Basis and the sides, but before and behind thicker, growing thiane and broad by degrees vnto the extremity : especially it is so in the vpper two which are called *dnales* and *pala*.

Pale, because they are very like vnto a pale: the superficies is on the outside, somewhat gibbous, and againe a little hollow on the inside. The other part of these teeth which is infixed in the law is toward the side flatted or compressed, and endeth in a sharpe point; for they root is but single; yet greater for the most part, at least as great as any the rootes of the great teeth: hence it is, that they easily fall out, especially those in the vpper law. In the extremities of these Teeth, when men are growne to some age, there is either no perforation at all, or if it be it is wondrous obscure.

Next to these are the Dog-teeth, called *Canini*, [tab. 11 fig. 3 char. 3] by *Aristotle* and *Galen* *κυνόδοντες*, not so much for their figure, or because they stand out of the gummies as Dogs teeth doe, as for their vse; for in dogs after the shreading teeth, there are two kindes of sharpe teeth; Some standing outward, others of a triangular forme. But a mans dog-teeth differeth from them both. They are onely two in each law, because a man is a milde and ciuill creature, whose strength consisteth more in wisdom then in fortitude of body, and therefore is not full of Dog-teeth, as other furious and rauening creatures are, and to break that which is hard two were sufficient. These go betweene the sharpe teeth and the plaine, the Shearers and the Grinders, and below at the gummies are broad and thicke, aboue sharpe and somewhat prominent beyond the course or order of the teeth. From the Shearers they differ, because they are thicker and their head somewhat narrower but not so sharpe. They are also harder, that if any thing by chance doe come betwixt the teeth which the Shearers cannot diuide, these may breake it; for the shredders were made to cut meat short, and these to breake that which is hard.

Their rootes, as those of the shearers are but single, yet infixed deeper, stronger also and lesse pressed, or narrow before then behinde. These rootes are longer then the single roots of the rest of the teeth, yet so that the vpper are sharper and longer then the lower. These they call the eye-teeth, not that they are so produced that they touch almost the lower circumference of the eye, for they do not go aboue the lower end of the wings of the nose, but because a portion of the nerue which moueth the eyes is deriued vnto them; and hence it is commonly and truly said, that to draw the eye-teeth is not without danger.

CHAP. XV.

Of the Grinding Teeth.

The great Teeth the Grecians call *μύλοι* or *μύλοι*, *Molares*, because by them the meat is broken as Corne is broken vpon a Mill. They are seated in the inner part of the mouth, and hidden by the cheekes: the reason of this position is, lest the meat already shred or broken, and by the tongue rowled vnto the teeth, to bee further ground should fall out of the mouth. In their vse therefore, and likewise in their forme they are like vnto a Corne-Querne, vnequall, rough, hard, broad and great: Rough and vnequall, for so they are more fit for comminution, and that is the reason why Millers when their stones are growne smooth doe picke them anew. But these Teeth in old men by long attrition doe become equall and smooth, and by reason of their perpetuall vse, are sooner broken and eaten out, then the rest.

Wherefore that part of these grinders which standeth without the gum is foursquare, and that square more perfect in the 3 hinder teeth: and though their tops are very large in fomuch as *Ruffus* in the eight chapter of his first Booke calleth them *παραζαι*, *Tables*, yet they are not smooth, but every one, saith *Eustachius*, hath a pit one or two in the midst: whence it cometh to passe that their extreame or outward parts are somewhat high. Those two that are next the Dog-teeth are heightned on the inside and on the outside, yet the first especially in the lower iaw doth sometime want his inward eminence: the third protuberateth or swelleth vp in foure corners: the fourth and the fift for the most part haue two eminences on the outside, on the inside but one. These cauities and protuberations meeting iust one with another do hold the meate faster that it fells not so easily from betwixt them.

They are the hardest, saith *Vesalius*, of all the bones, that they might not so easily weare away; broad also and plaine the better to leuigate the meate that is already shorne and broken by the other teeth; for it was not fit that a man should swallow his meate before it were perfectly ground: beside being so ground, the heat and moisture of the mouth assisting, there is made in the mouth a rude inchoation or beginning of concoction.

They

Dog-Teeth.

Two in each law.

Their rootes.

Eye-teeth.

The Grinders.

The forme.

Magnitude.

They are called also *σοφιστοι*, not because their insertion is by way of mortize, for that is common vnto all the Teeth, but *απο της ρομφαιδσεως*, that is, from the rough superficies of a Mill-stone, whose figure and vse the vpper parts of these grinding teeth doe elegantly imitate. In Magnitude they differ, for the middlemost are the greatest, and those on each side lesser. The third is the greatest of all in Men, in Apes the fourth and the fift; for it was not fit that the internall capacity of the mouth which groweth narrow as the anterior part doth, should haue teeth so great as the middle where it is broadest of all. Sometimes to the fourth or the fift (but in the vpper iaw rather then the lower) there is adioyned as it were a halfe tooth, for Nature con- tending to make more grinders, is hindred by the narrowness of the place, and therefore is constrained to ioyne them together.

Number.

Their Number is commonly in the vpper and lower lawes on each side five, that is in all twenty. The reason why there are more grinders then shearers is, because Nature doth vse according to the largeness or narrowness of the fissure of the mouth to allow creatures more or fewer of this kinde. Man whose mouth is very narrow, and whose teeth were specially giuen him to chew his meate, hath therefore more grinders then shearers or dog-teeth: on the contrary in rauinous creatures there are more shearers and grinders, because they vse them as weapons. Hence it is, that in men there is little difference in the number of their Shearing or Dog-teeth, but of Grinders there is great variety: some- times five, sometimes foure, sometimes sixe. *Eustachius* did neuer obserue so few as three, sauing once in a Cardinall. It may be his lawes were short. And this variety *Galen* makes mention of, although there be no such variety in Apes; whence saith *Eustachius* (and the ob- seruation is very good) it may well be concluded, that *Galen* did vse to cut vp not apes onely but men.

The teeth of wisdom.

The two latter grinders both in site and generation, are called by *Hippocrates* in his Booke *de Carnibus* *σοφιστοι*, the Teeth of wisdom, because when they grow vp a man beginneth to be wise: for they arise about the fourth Septenary, that is, at 28. yeare old, at what time men are, or should be temperate and moderate. In the breeding of these teeth there is some- time great torment and paine, and therefore *Auicenna* calleth them the teeth of Sense. They spring vp sometime in old age, and therefore *Aristotle* calleth them *ραντις*, because they per- fect the age or groweth: the Latins call them *Genuinos*, to which Teeth this is peculiar, that they doe not begin to breake out till all the rest haue bene a good while perfect. Sometime also they onely perforate the Gummies but rise little aboue them; sometimes they lurke all together in the iaw, and are couered with the Gummies, sometime they are not created at all.

Their rootes in Apes.

The roots of these Teeth are perpetually of one forme in Apes, as *Eustachius* elegantly de- clareth; for in them the grinders of the vpper iaw haue three roots: of the lower iaw two, ex- cepting sometimes the fift; the fourth as it is the greatest, so are the roots thereof greatest. In Men their roots are not alwayes of one forme, yet most what they are many and alike: some- time in the fift of the lower iaw, (in the second also *Eustachius* obserued the same) which be- cause of his magnitude a man would thinke should haue many roots, there is but one, thicke and perforated with one broad hole. Other roots of the Teeth haue an equall or vnequall superficies, and within two or three holes skilfully thrilled and disseuered by thin scales, much like a Hony-combe. In the fift grinder there are three, in most of the rest two. Oftentimes the roots grow together, sometime they are separated, sometime a man cannot perceiue so much as the line that parteth them.

Their figure.

The Figure also of these Roots is diuers, for some are round, others streight and accute, others obtuse, plaine and crooked, They differ also in magnitude, the roots of one tooth be- ing thicke sometimes, sometimes narrow, of another short, of another long, of some broad and thin, yet for the most part the roots of the vpper teeth are long and of the lower teeth shorter.

Situation.

They vary also in situation, some touch one another, some growe neare but touch not, some straddle one from another like the feete of a stoole. Againe, some stande off one from another, but yet are so incurued that their extremities do touch, others running foure wayes are in their ends most of all disioyned, and these in drawing of Teeth are sometimes broken and put the man to cruell torment.

If there be three roots, especially in the vpper iaw, one runneth inward and two out- ward. To conclude, commonly the two vpper grinders which are next to the Dog-teeth are fastned into their sockets with two roots, the other three with three. Sometimes, the

fift

first hath foure which is rare. Again, the two lower Grinders which are next to the Dog-teeth haue but one roote, the three others two. Those Teeth which we call *Genuini* or *Teeth of wisdom*, haue very short rootes, partly because that portion of the iaw will not admit a deepe insertion, partly because in the leuigation or chewing of meat they are not in so much vse as the rest. Wherefore the roots of the grinding Teeth of the lower iaw are fewer and shorter then those of the vpper, because the substance of the lower iaw is harder and more solid, and therefore better able strongly to containe the Teeth, and to beare their waight; but in the vpper iaw, which is more rare and soft and wherein the Teeth hang, and therefore are more subiect to fall out with their owne weight, their roots are longer, the better to fasten them, for they needed more ties as it were to binde them and to containe them within the iaw.

Hence it is that where the roots are shorter the Teeth are drawn with lesse danger, but with more labour where they are many, especially if the roots grow vnto the sockets.

The roots of all the Teeth are perforated euen into their internall cavities, yet this perforation in perfect and growne Teeth is very small, and that in the sharpe point or top of the roote through which a veyne, & an artery and a nerue are admitted; of which Vessels we will speake in the next place, but briefly because we haue touched vpon them before.

CHAP. XVI.

Of the Vessels and Sense of the Teeth.

Through the holes of the roots of the Teeth all manner of Vessels doe run and are diuersified in their internall cavities; veines first to bring them plentifull nourishment. Now it was necessary that the Teeth should alwayes grow, because in mutuall attrition they weare one against another, and this we may certainly conclude by our owne experience. For if a tooth fall out or be drawne, that which groweth opposite against it will be longer then the rest of the Teeth of his owne ranke, because it is no more worne by the Tooth that before was opposite against it, the rest of the Teeth by their mutuall attrition in chewing of the meate are impaired and againe so much increased.

Arteries also doe enter into the Teeth to preserve and keepe their naturall heat; hence it is that in inflammations there is a beating or pulsing paine felt, such as fleshy parts feelee when they are inflamed. And this *Galen* first of all men obserued in the 8 chapter of his first booke *de Compositione medicamentorum secundum loca*, for he found in himselfe not only paine but a pulsing paine in his Teeth, whence he concluded that there was one paine in the Gums, another in the very substance of the Tooth. Yea without any inflammation of the Gums sometimes there is paine in the proper body of the Teeth, sometimes in the nerue.

And againe vnlesse vnder the Tooth there were an artery, how could so much florid and pure bloud issue when the Tooth is perforated, which *Eustachius* obserued in a man that fell into such a flux of bloud from his tooth that he had like to haue died vpon it.

They haue also nerues soft and slender which come from the third coniugation commonly so called, and runne through their rootes in their cavity euen from their first conformation; where they are disseminated, and their small fureles are mixed with the mucous matter of the Teeth; hence it is that when that mucous matter is become bony yet it easily consenteth with the nerues, and so the Teeth become sensible; whereas to other bones there are no nerues at all conuayed which may be dispersed into their cavities. And therefore it is truly said that bones want nerues although the membrane which is called *Periostium* haue sense and nerues in it. Wherefore when this *Periostium* which is of exquisite sense is affected, the paine may be thought to be in the bones themselves when it is only in the membrane: so in a Cicatrice which hath no sense we imagine we feelee paine when indeed the paine is onely in the neighbour parts; and the membrane which inuesteth the Liuer being affected we thinke we feelee paine in the Liuer whereas the *Parenchyma* or substance of the Liuer it selfe is insensible: vnlesse any man will say that the bones haue sense by the helpe of the Sensatiue soule by which they subsist: and yet that very obscure, because the hardnesse of the bones doth very much resist any such sensation; and thus we may say that bones do differ from plants as being particles of a sensatiue creature.

Their perforations.

Veines.

Arteries.

Nerves.

How teeth haue sense.

These

How to demonstrate the Vessels of the Teeth.
Eustachius.

These nerves of the teeth are very small, yet in our Table we have made them large, imitating therein *Vesalius* and others. But by what order and manner of dissection, we use to make demonstration of the vessels and nerves of the Teeth, saith *Bauhine*, we will now relate as we learned it out of *Eustachius*.

These vessels are better demonstrated in the iaw of a great creature, as for example, in an Oxe, then they are in a Man: and againe the administration is easier in the lower iaw then in the upper. We take therefore the lower iaw of an Oxe and open it on the inside, and presently we meete a cavity full of marrow, together with the nerve inuolued in a membrane; when we have remoued the marrow and slit the membrane throughout his length, then may wee perceiue the nerve made as it were of many strings, betwixt which do run propagations of veines and arteries. Moreover, if you remoue this membrane with the surcles of the nerves and vessels a little vpward from the bone carefully that you breake them not, you shall perceiue some fibres distributed from the membrane not vnlike the Lawny threds of a cobweb. In like manner in the iaw of a Ramme certaine fibres do penetrate the bony partition which is betwixt the Nerve and the Teeth, but these fibres are most conspicuous at the roots of the grinders.

From these *Grinders* vnto the *Dog-teeth* and the *Shearers* there is a nerve conueyed accompanied with an artery: the nerve is deuided into two; one part of it, through a hole in that place, breaketh vp at the lower Lip, and a branch of it runneth along vnto the *Shearers*, and affoordeth a small surele to euery one of them; another portion of it is ioyned with the vtter part of the roots: the second part (which is also the slenderest) beareth into the cavity of the teeth, and may euen without any greater difficulty be discerned euen in men.

And truly it is a strange thing that the *Shearers* and *Dog-teeth* which are the lesse and haue but one roote, haue notwithstanding allowed them great and conspicuous surcles of vessels attaining to their insertion by a broad and open way; whereas the *Grinders* which are the greater (and haue three, sometimes foure roots) are allowed but small and capillary surcles made of the former, doubly, trebly and foure-fold deuided, and creeping obscurely into their insertion.

Againe, if a *Grinder* or a *Shearer* be gently and by degrees drawne out of his socket, you shall finde to arise with it out of the cavity of the iaw very small fibres which are ioyned to the roots of the Teeth: you may also obserue that the parts of the bony partition are full of a mucous substance which is not vnlike to that whereof the teeth and their huls or huskes are generated.

Againe, when the Tooth is drawne, in the extremity of his roots you shall find a matter partly mucous partly fibrous, which cartieth a resemblance or shew of a nerve, a veine and an artery.

But if you deuide the Tooth in the middest you shall find a mucous substance wouen with vessels and some fibres: but these things may be better seene in the iaw of an Oxe or of a Ram then of a Man; and yet euen in a man diligent search will find them out, though they be not so conspicuous.

Wherefore who can deny but that there is a Pulsatiue or beating paine euen in the inner part of the tooth, as *Galen* and *Eustachius* haue witnessed, when he shall perceiue an artery and a nerve attaine therinto? For veines, why should we not likewise beleue that they enter into the Teeth, when we see it sprinkled with bloud in men; and in Oxen may manifestly perceiue the vessell it selfe? for it is in the tooth as it is in that coate of the eye called *adnata*, as long as a mans Eye is well disposed the veines therein are not visible, but then onely become conspicuous when it is inflamed.

Of the sense of the teeth.
Divers opinions of Anatomists.

Concerning the Sense of the Teeth, the opinions of Anatomistes and Physitians are very diuers. Some thinke they haue no sense at all, because they are bones and may be filed without paine; others thinke they haue Sense, but that of themselves without nerves, as other bones haue: and these men imagine that the paine of the tooth is without it, that is, in the membrane which compasseth the socket: others thinke they liue and haue Sense by their inbread heate. *Aristotle* determines that they feele cold sooner then heate, and are more affected by it: *Galen* saith they are pained, they beate and receiue soft nerves. But the question may be asked what part of the tooth hath this Sensation? *Varolius* answereth the body of the tooth, but on the inside onely. Others say that the whole Tooth indeede hath Sense, but the whole Tooth doth not feele paine; it perceiueh the first and second qualities

qualities, but the first qualities onely doe paine it, because they exercise their power vpon the roots of the teeth, into which certaine small nerues doe penetrate. This was *Archangelus* his conceit, and *Laurentius* hath almost the same. The whole Tooth (saith he) doth feelee, but more exquisitly on the inside, more dully on the out.

Another question may be asked, whence comes the sensation that paineth them? some answer, that it is by reason of the nerues and of their proper substance, so saith *Actuarius*. *Falopius* thinks the paine comes by reason of a thin membrane compassing about the inner cavity. Others ascribe the cause to the nerue and the membrane ioyntly: others to the nerue which cleaueth to the neighbour parts and to the roots of the Teeth onely. Others to the nerue that entreth the Tooth and a membrane that cleaueth to the roote thereof as it were a *Periostium*. Others to a nerue which penetrateth the substance.

These and such like are the diuers opinions of Anatomists concerning the sense of the Teeth. *Bauhine* interposeth his opinion on this manner.

The teeth, saith he, do feelee, and the faculty of sensation is communicated to their substance by the mediation of a very thin membrane which compasseth the inward cavity of the Tooth lightly hanging vnto it, and also of a soft nerue which attaineth into the same cavity: thus the Teeth haue a proper kind of Touching which we cannot in words so well expresse as by instance. For vpon the eating of sowre or sharpe meates the Teeth are affected with a kinde of stupor, and then we commonly say our Teeth are set on edge, which kind of sensation is proper only to the Teeth and the Gums, and is nothing else but a Symptome of the rouching faculty.

But we must conceiue that each part of the Tooth is not equally sensible, but that the inside which is nearest to the nerue and the membrane is of quicker apprehension then the outside; for the outside, partly because of the spisse and hard substance which like a shell couereth the inward part of the Tooth, and doth not admit the power of the nerue or the impression of the animal spirit, partly because it is continually accustomed to the mutations that come from the ambient ayer is not so sensible. Euen so we see that the callous skinne in the hands and feete of a labouring man is almost altogether without sense, though the skin it selfe naturally disposed be very sensible.

Wherefore that part which is without the Gums or the shell of the Tooth is not offended by hard and rough things, for though it bee cut or filed, or burnt with a hot yron, yet it is not pained, neither is there any sense or signe of sense following thereupon, especially the height or top of the tooth which was made solid to breake the meate, and therefore the cavity not attaining so far the nerue also commeth short of it.

The reason why a part of the body of the tooth is not pained by fire or by hot rion, *Aritius* saith is knowne onely to the Gods. As for vs we can say nothing but that it is a peculiar to the teeth that they are not equally affected either by all things that make alteration in them, or by those things which might offend them; but are more affected by heat and cold then by any other qualities, and by cold more then by heate, yet to giue some satisfaction, we say, that the teeth are not offended by moist or dry by soft or hard things because their qualities are not so suddenly communicated to the membrane or to the nerue. But they are affected by hot and cold things because the animall spirits which are contained in the substance of the tooth and diffused through the same, are thereby altered; for those actiue qualities do pierce on euery side, affecting and changing together with their substance the animall spirit and by succession also the membrane and the nerues. And truly it is very reasonable to imagine that in the substance of the teeth there are great store of animall spirits more then in other bones, first because they receiue soft nerues into their cavities, and againe because their internal substance is somewhat rare, made of a mucous matter condensed or thickned.

Obserue also that the paine which is felt in the substance of the tooth differeth much from that paine which is in the Gums, either from their distemper or from any flux of humor into them, and from the payne which is felt in the nerue that runneth vnder the roote of the Tooth.

The vse of their sensation is thought to be, first that being exposed to outward iniuries, and hauing no *Periostium* to compass them about; it was fitte they should haue an ingenite principle of Sense that they might be able to discerne betwixt that which is profitable and hurtfull.

Again if we will beleue *Galen* in the second Chapter of his 16. Booke de vsu partium, as all the other parts of the mouth, so likewise the Teeth doe after a sort discerne of sapor

Bauhine's resolution

Great store of animall spirits in the Teeth.

The vse of their sense.

or

or Tastes, and for that purpose they receiued soft nerues. For as the skin hath Sense, yet through the cuticle or scarffe-skin which is not sensible; so the marrow of the tooth is apprehensive of tactile qualities through the bony part, like as the nervous membrane which is vnder the nailes doth feele heat and cold through the nailes which haue no sense at all. And so much shall haue beene sufficient to haue spoken of the Sense of the Teeth. Now we come vnto their cavities.

CHAP. XVII.

Of the inward cavity and Membrane of the Teeth.

The cavity of
the teeth.

WE said before that the Vessels and the Nerues did enter into the cavities of the teeth, and therefore it would be very fit we should acquaint you what this cavity is.

All the Teeth are hollow on the inside, [tab. 11. fig. 3. B] but this cavity is greater or lesser according to the magnitude or figu. of the Teeth, which thing also *Aristotle* acknowledge in the 7. chapter of his 3 booke *de historia animalium*, where he saith that the teeth are bones partly concavous and partly solid. Notwithstanding some new Anatomists haue been so impudent as to challenge to themselves the inuention or finding out this cavity. *Galen* indeed in those bookes of his which are extant, doth not write how great or what a kind of cavity this is, nor yet what is contained therein; yet because oftentimes he makes mention of the *Dennes* of the Teeth, it is not likely that he was ignorant of them; for if he had beleueed that the teeth in their first originall had had no cavities, it had beene an idle thing for him in vehement paine of the teeth to command that their solid substance should be perforated with a small wimble or piercer, in the ninth chapter of his 5. booke *de compositione medicamentorum secundum loca*. Again, *Hippocrates* in the 4. *Epidemi*an reporteth that a Childes Teeth were eaten with a corroding vicer, those especially that had cavities or were hollow, whereby *Hippocrates* doth insinuate, first that the substance of the Teeth may be corroded, and secondly that they haue a naturall cavity in them.

The humour
therein.

This cavity is in children of seuen yeares old and somewhat vpward very large, and circumscribed with a thin scale very like vnto a hony-combe. It is also full of a white humour, not of marrow, such as we may see in the sweet-tooth of a Calfe when it is brought sodden vnto the Table, but this humour in proceffe of time is dried, becomes harder, and for the most part turnes bony, and so the cavity is euery day diminished; yet so that in the midst at the roote there remaineth alwayes a *Sinus* which scarcely reacheth aboue the height of the Gums: for it was necessary there should be an empty space left, because of the insertion of the vessels and the dilatation of the artery: yet some men affirme that the pulsation we feele in our teeth doth not proceede from the beating of the artery, but from a spirit or ayre moued, as sometimes we find it to be in our eares.

Three cavities
in a Calues
tooth.

These things saith *Eustachius* are best perceiued in the Grinding teeth of an Oxe broken; and in a Calfe and a Lambe each grinder hath three cavities, one anterior another posterior and the third in the midst; and the middlemost cavity is perforated with a crooked hole like the letter C which reacheth as farre as to the top of the Gums: in the two other cavities there is a mucous matter contained, which for the most part as the Tooth growes perfect turneth bony. Beside, because in these creatures we find oftentimes two, sometimes three, sometimes foure grinding Teeth ioyned together, Nature to make a mutual consent between them, hath perforated the bony partition with a transuerse hole, through which a matter like a small membrane passeth out of one cavity into another, as furcles of vessels do passe through their perforations.

This cavity is compasse d with a membranous substance, which *Falopius* and *Laurentius* call a thin membrane. *Goreus* saith it is a production of the *Pia mater*. *Columbus* esteemeth it to be made of a complication of veines, arteries and nerues, which imbibeth or sucketh vp the matter that falleth vpon it, from whence come the greatest and most intolerable paines of the tooth-ach.

And indeed this membrane is of most exact Sense, and by it the Teeth are so apprehensive of heate and cold: yea saith *Bauhine* we consent with *Columbus* herein, that the fluxe of humour out of the Brain vnto this membrane is the true cause of the greatest paines in the teeth which do so long endure as the humour is detained in the Membrane; or till the braine bee purged, and so the cause of the fluxe be taken away.

By

By reason of this cavity if the teeth be perforated by an affluence of sharpe humors, which perforation doth reach to the cavity, then are the teeth quickly rotted even vnto the roots; againe in this cavity, especially the erosion and putrifaction of the teeth doth begin. In it groweth that delourous rottenesse, and in it sometimes are wormes gathered which doe miserably excruciate and punish the patient. The vse of the cavity is, that by it the teeth may be better nourished, and receive the faculty of sensation.

How the teeth
rotte.

The vse of
their cavities.

CHAP. XVIII.

Of the generation and vse of the Teeth.

Concerning the generation of the Teeth, there are diuers opinions; some thinke they are generated within the Wombe, as *Columbus* and *Eustachius*; some without the wombe, as *Aristotle*; some partly within and partly without, as *Hippocrates* who maketh a threefold time of their generation, in his Booke *de Carnibus*, of a threefold Aliment which ministreth matter vnto them. The first is from the sustenance they receive in the wombe; the second is after birth by the Milke which the child sucketh; the third is after he hath cast his teeth by the meat and drinke that he eateth whereby new teeth are engendred: for, saith he, whatsoeuer is glutinous in the Aliment that maketh the Teeth, but the fatty part (which heere is more plentifull then in the matter of the rest of the bones) is exccited by the power of the heat. Also (saith *Laurentius*) as this threefold kind of Aliment differs in thicknesse, so doth the solidity, hardnesse and thicknesse of the teeth vary, for those teeth that are engendred of the Aliment which the infant vseth in the wombe, or when he suckes his mothers brest, are but soft, and doe easily fall away, but those that are made of more solid meats are also firmer.

Diuers opini-
ons conce-
ning the ge-
neration of
the teeth.

The truth is that they are generated in the wombe together with the rest of the bones; with which they are not delineated but formed and absolved by degrees: wherefore they lye for some time imperfect in the lawes, neither do they all breake their prisons at the same time, but some sooner, some later, according as the necessity of Nature doth require. And this is the cause why some made a double time of their generation, one in the wombe; another out of the wombe.

The truth.

In the wombe after the generation of the lawes there are twelue Teeth formed, foure of which are *Shearers*, two *dog-teeth* and six *Grinders*, all which doe want roots, and lye hid in their sockets, on euery side compassed therewith, and the gums whole about them. And this may be seene in the iaw of an abortiue infant or other creature, yea if it dye presently after the birth; for if you cut vp the law you shall finde Teeth therein. Some haue bene borne with their Teeth out of their gummies, as of old time *M. Curtius Dentatus*, and *Cn. Papyrius Carbo*. Of later times, the same is reported of *Richard Crooke-backe* the Vsurper.

The substance of the teeth being yet imperfect is partly mucous and partly bony, for if you take away the huske of the Tooth, (for there is about euery Tooth such a white, mucous and slimy substance somewhat membranous wherewith the tooth is couered, which also is so much the more mucous by how much the tooth is the softer and the younger) perforating it in the vpper part, that the end of the Tooth may peep out, then shall you perceiue that the tooth is partly bony, partly mucous; for that part which was to rise aboue the gums is fashioned into a white scale, thin and excauated or hollow like a Honey-combe, and so the vpper part of the Tooth is bony, hard and hollow. The other part which should haue remained infixed in the law, is soft, moyst and mucous, like the substance that is in a young quill.

The substance
of the Teeth
diuers.

Third hard
part.

The soft part.

This substance seemeth to haue fibres and threds and to be couered as it were with a thin coate, for the superficies thereof is like to a smooth tunicle fastned and conioyned to the substance that it containeth: wherefore a resemblance of the generation of the teeth wee haue some-what expressely in the generation of a quill: for the part which is without the skin is horny and hard, but that which is within the wing is softer and moyster, yea sometimes like blood or congealed Phlegme. This soft part of the teeth as they breake the flesh hardneth by degrees, and by degrees becommeth bony. Sometimes also it is hollow within and formed into roots.

The hull or huske of the Tooth whereof we spake euen now serueth in stead of a Ligament, for by it the rooth is fastned as with glew to the socket and to the gums.

In Infancy the Teeth be within the Gums that they might not byte the Nurses nipple: the seuenth moneth they begin to breake out, or later saith *Hippocrates*, if the Infant do tooth with a Cough, and then they are troubled with Agues, Convulsions, Scowrings and such like, especially when they breede their *Dog-teeth*. *Galen* rendereth a reason, because when the Gums are perforated by the Teeth the paine is as violent as if a goade were thrust into the flesh, but indeed the teeth are more painfull then goades, for if a goade be once fastned it resteth, but the tooth issueth still to the extent of his augmentation.

The times of
dentition.

The first.

The Teeth breake out not altogether but the vpper sooner then the lower, and the Shearers sooner then the Grinders: that they issue later in men then in brute beasts (for the Elephant, saith *Aristotle* in the 5. chapter of his 2. booke *de hist. animal.* breedeth his teeth as soone as he himselfe is borne) the reason is saith *Aristotle* because a man about all creatures hath less of that earthly excrement whereof they are ingendred. But because the first Teeth and those that follow them which are though to be regenerated, doe lye hidden in the iaw-bone, therefore we rather say that the cause of their late issuing in men is to be attributed to the good will and pleasure of him that made them, who moderateth all things according to his owne wisdom; yet when the childe comes to chewing, that he might cease to be troublesome to his mother, and not lye alwaies lugging at her breasts but fall to stronger kinds of meate, therefore at length Nature puts them forth; for euery particle is then accomplished when Nature standeth in neede thereof, and this is the reason why the Teeth are not formed till after the birth. For this cause also saith *Aristotle* the Shearers doe yssue before the Grinders, because the meate is first shred before it be ground.

Dentition or the breeding of the teeth begins about the second yeare, sometimes sooner, but then saith *Hippocrates* in his booke *de carnibus*, they are ingendred of an ill humour. The first Teeth that arise are the fore-teeth; *Democritus* saith because their sharpe ends make way before their due time. *Aristotle* reprehends him and giueth another reason, because that which is sharpe doth soonest grow blunt: and therefore Nature sendeth a supply of others; the broad Teeth are not blunted at all but onely leuigated by attrition, and this is *Aristotle* his conceite in the 8. chapter of his fift booke *de generatione animalium*.

When the first Teeth about the seuenth yeare are either drawne or thrust out by those that come vnder them, then do those first Teeth appeare soft and as it were hollowed: and therefore some haue thought them onely Appendances of certaine roots left in the iaw, of which roots, as it were of seede, a new hope or succession of teeth is brought forth. *Vesalius* therefore counsels vs to take heed that when a childes tooth is broken by accident we do not draw the roote, for then haply the tooth will not grow againe. But Anatomy teacheth vs the contrary, that is to say, that there is no coniunction betwixt the imperfect teeth that fall at seuen yeares of age and the perfect that arise after. Nay they do not so much as touch one another, for there is a partition in the middest betwixt them before the new tooth can breake forth. And thus much of the first time of the generation of the Teeth within the wombe.

The second
time.

The second time of their generation is without the wombe, about the seuenth yeare, and these teeth are commonly thought to be regenerated; but to say truth and to speake properly, they are then neither generated nor regenerated. For together with the first Teeth in the beginning of generation they doe receiue with the rest a rude kinde of forme, and are made of the same matter; otherwise we must be constrained to confesse, (and that were very absurd) that Nerves, Vessels, Ligaments and Membranes which are spermaticall parts and doe consummate the frame of the Teeth, doe begin their generation after the Infant is borne seuen yeares, more or lesse. It is true indeed that these latter Teeth are not sooner absolued or perfected then in the seuenth yeare or thereabouts, and the proportion seemeth not to be much amisse, for they first breake out of the Gums about the seuenth month, and the second about the seuenth yeare. And this proportion *Hippocrates* in his booke *de septimestri partu* standeth much vpon, not only in the production of the Teeth, but also in other mutations in the body of man.

Galopius conceiueth that the latter Teeth are made of the same matter with the former by the seminary faculty which remaineth in the iawes, and *Eustachius* confesseth that if you remoue the bony partition that is betwixt the first and the later teeth, you shall finde the feedes of the Teeth one vnder another, I meane of the Sheares and the Dog-teeth, but

but of the Grinders he neuer found any feedes; and yet he thinketh it reasonable that they should have a rude originall in the wombe which is accomplished afterward at leasure.

The teeth which about the seventh yeare breake out, or as some say are renewed, are in either iaw ten, foure Shearers, two Dog-teeth, and foure Grinders or Maxillaries, that is, two next vnto the Dog-teeth, and two that are called *Genuini* or *Teeth of wisdom*. The shearing teeth when they breake forth do thrust the first shearers out before them and issue betwixt the two first, the second, and the Dog-tooth that is next vnto them. But if the former teeth will not fall or be not pulled out, or if the latter issue before the first fall, then the latter worke their way through new sockets and turne in the vpper iaw outward, in the lower iaw inward, so that there seemeth to arise a new row of teeth, and this indeed hath deceiued many Historians and some Anatomists also.

The Dog-teeth also do fall out and the place of the succeder is a little on the one side the roote of the former.

The reason why the teeth about the fourth fift sixt or seventh yeares do grow loose, is because the sockets do continually increafe and the teeth are but soft and therefore doe soone perish, because the harder Aliment which from thenceforth accreth vnto them is nothing conuenient to their substance, and then they putrifie and fall away: but those teeth that breake out at the seventh yeare receiue nourishment agreeable to their substance, & therefore do continue as long as their nourishment is supplied. Among the grinders the two first doe sometimes thrust out their predecessors, but for the most part they arise at their sides and increafe the number: those two that are called *Genuini* do neuer thrust out them that were before them, but yssue sometimes in extreame old age, in the very ends of the iaws; yea *Aristotle* reporteth that these teeth haue arisen not without great paine after fourescore yeares. Notwithstanding this is more rare in men then in women. *Hippocrates* in his booke *de Carnibus* witnesseth that these teeth which grow vp so late doe wax old together vnlesse by mischance they fall out or perish.

The manner of the generation of the teeth *Falopius* thus expresseth. The quickening faculty by an aërie spirit makes the bone hollow; at the same time is ingendered a membranous huske which hath two ends, one posterior whereat a small nerue, a veyne and an artery doe meete. The other anterior whereat hangeth a neruous tayle like growne Malt: and this taile creepeth through a narrow perforation of the bone to the side of that tooth which hath a successor and so passeth vnto the Gums.

In the foresaid huske there gathereth together a white and slimy matter, and the first part of the tooth becomes bony when as yet the latter part is soft, euen so as we said it was in the teeth formed in the mothers wombe.

Euery tooth issueth through that hole dilated, through which the tayle or beard of the huske was transmitted. Instantly the huske is broken and becommeth as we said before a ligament to the tooth, and the tooth it selfe issueth naked and hard, notwithstanding the hardest part of it receiues a further perfection by induration of his matter without the Gums.

The primary and first vse of the teeth was to deuide, to breake, or chew or mitigate the meate and so to prepare it for the stomacke. Againe, another vse of the teeth is for the forming of the voyce, for Shearing teeth are of great consequence to true pronunciation of letters or words; and hence it is that those that want their teeth cannot so well pronounce R, S, X, Z, yea it is thought that the shearing teeth in men haue no other vse but onely for elocution although the Infant doth not lightly speake before he haue all his teeth, or at least some of all kindes. When he hath a few teeth he will mumble and as it were record, but cannot articulate plainly till he haue all, yet these shearers doe not equally assist vs in the pronunciation of all words, onely they make the prolation of some more cleare and facile. Those words that are formed of T and R cannot be pronounced without the shearing Teeth articulary, for they require that the Tongue should rest vpon the fore Teeth. *Laurentius* saith the Teeth were made for ornament, but *Homer* more wisely, that they were giuen to men to keepe their Tongues within compasse. *Bauhine* thinks that the Teeth of themselves are not onely no ornament but a fearefull sight, and therefore Nature compassed and distinguished them with Gums, couered them with the lip as it were with a buckler the better to breake and change the ingresse of the outward ayre. Those creatures who are able eyther with the hornes to defend themselves as a Bull and Cow, or with their hooves to offend their aduersaries, those creatures, I say, haue teeth onely to cate withall. They that haue saw-teeth do both mitigate their meat by them and

The number
of the Teeth.

How they
issue.

The manner of
their genera-
tion.

Their vses.

stand vpon their guard with them, for they are giuen to such creatures both to offend and to defend, whereas a man hath his hands to defend himselfe.

And thus much shall be sufficient to haue said of the Teeth, their Sockets, their Nature, Figure, Magnitude, Number, Site, Articulation, Kindes, Vessels, Sense, Cavity; and finally of their Generation and Vse.

And thus we haue brought to an end the history of the bones of the Scull and of the Face. Another bone there is which belongeth not indeed to the head, but much lesse vnto the Trunke or the ioynts, whose history we will therefore insert in this place because it is neare vnto the Head though it be not of it, and that is the bone *Hyois*.

CHAP. XIX.

Of the bone *Hyois*, called *Os gutturi*.

The bone;
Hyois.
His situation.

That bone which from the similitude it hath with the letter *v* is called *Hypsiloides*, or shorter *Hyoides*, [tab. 11, fig. 4, and 5,] is seated in the chops before the top of the Larynx, and therefore is also called by *Galen* *Os gutturi*. It lyeth like a foundation vnder the basis of the tongue, and is extended directly along the necke, and the figure of it is farre other in men then it is in brute beast. It representeth the letter *v*, for the termination thereof is not in an acute angle but in a bow or bent, and therefore is not much vlike the lower iaw, for it is not only curued like a bow as that is, but also determineth into two processes. The figure of it was thus made that the way might be left open for the meat to passe into the stomach and for the breath to passe and repasse to and from the Lungs, for as we said euen now, it is placed iust before the chops and the Larynx.

Figure.

The parts.

Although this bone be expressed by one single name yet is it not one bone but compounded of many, at least of three, at most of thirteene, but for the most part in ancient men it consisteth of eleuen bones which are ioyned together by a laxe or dissolute composition, with a gristle betweene them that they might better yeelde and giue place when they are moued.

The ends of this bone do not touch the ends of any other, and therefore it is fastened to the neighbour parts, otherwise the tongue could not haue rested vpon it as vpon her basis. The continuity therefore that the bone *Hyois* hath, is by the mediation of muscles and ligaments, for it is continued to the lower iaw about the Chin, to the brest-bone, to the shoulder-blades, to the Appendix of the Nowle called the Bodkin, to all these I say, by the kind of Coalition which we called *Synsarcosis*, for it is bound by flesh or *Flesh bound*. Of all the bones, that is the first which is in the midst, greater and broader then the rest, and as it were their basis. [14, 11, fig. 4, ABCD] On the anterior and exterior part that regardeth the mouth, it is conuex and determineth into an obtuse or dull angle, which we may feele in our selues about the Throatt although the processes do lye very deepe. This angle was made partly to secure it from outward iniuries, partly to afford an implantation to some muscles. On the inner or posterior side which regardeth the chops it is hollow, [tab. 11, fig. 4, D, fig. SP] from which hollownesse two muscles of the Tongue do arise, and beside the cavity giues way to the Epiglottis to open and lift it selfe vp.

Cavities.

It hath three bosomes; aboue, a transuerse depressed bosome [c] to admit the second paire of muscles which are proper vnto it; in the midst it buncheth out. [*] In the sides of this *Sinus* there are two other cavities, one on the right hand another on the left, which giue way vnto the first paire of muscles that are implanted into the sides of this bone.

Processes.

It hath also two processes on either hand arising out of the basis. [EFIK] which some call *Hornes* or *Ribs*, by which it is ioyned to the two lower neighbour bones.

The two lower.

The two lower which make the second and third bone [EP] do consist on either hand of one bone: they are shorter and broader then the vpper, and are fastened to the bottome of the sides of the first or middle bone [tab. 11, fig. 4, G] by the interposition of a gristle and a good broad gristly ligament. At their extremities [HH] because they are not ioyned with any other bone, they couple themselues with the processes of the shield-gristle of the throttle, and these processes together with the middle bone make the shape of the letter *v*.

The two vpper.

But because this bone hangs like a meteor, it would not haue had sufficient strength if it had bin only ioyned with the gristle of the Larynx; nature therefore adds 2 other processes to bend it

side, Nature hath provided muscles which ballance it and keepe it equall, and not only so, but also certaine strong Ligaments in the two sides of the bone *Hyois*, yea and others that are gristly and round which she hath inserted on each side; and as if all this were not sufficient, it is fastned by certaine mrmbranes not onely to the *Larynx* and *Epiglottis*, but to make it more stable, to the Gullet also.

The uses of
the bone *hyois*.

The uses of the bone *Hyois* are very great (though it be but a little bone) and very many. It was framed therefore for the tongue and the *Larynx*: first to be a *Basis* for the tongue above which it might be moued diuersly and suddenly, like an Eele saith *Laurentius*. The second use of it is to lift vp the *Larynx*. A third, that from it many muscles might take their originall, that is to say, some of the tongue or the fourth payre. The fourth payre from the first of the middle bone, the fift payre from the fourth and fift bone when they are there, when the fourth and fift are wanting then it ariseth from the second and third bones.

The muscles also of the *Larynx* take their originall from hence: the *anterior*, that is to say, the beginning of the first and fourth paires of the foure common muscles from the lower part of the first bone: and thus we see how the bone *Hyois* was ordayned to establish the muscles of the tongue and the throtle. And so much of the bone *Hyois*, now we proceed.

CHAP. XI.

Of the Spine in generall.

WE deuided the *Skeleton* before into three parts, the Scull, the Trunke and the Ioynts. The scull we haue prosecuted as narrowly as we could, the Trunke we also deuided into the Spine, the Chest, and the bone without a name. Vnder the name of the Spine we comprehend all that which is extended from the first Racke bone of the Necke vnto the *Coccyx* or Rump: and this the Grecians call *σπονδυλός*, because the backpart of it is sharpe and spinie. It is called also *dorsum* or the Backe, because the Backe is the greatest part thereof.

What the
Spine is.
The dignity
thereof.

This Spine is the habitation or seat and defence of the Marrow as the Scull is of the Braine. For because the dignity or worth of the Marrow of the Spine is equall to the worth of the braine (for it is the originall of all the sinewes excepting seuen coniugations, and therefore is called the Braines Vicar or Substitute) Nature was no lesse carefull of the preservation thereof then she was of the Braine it selfe. As therefore the Braine was compassed with the bones of the Scull as with a Helmet, so the Spinall Marrow is walled in on every side by the Racke bones of the Chin.

Why the spine
is hollow.

This that nature might the better accomplish, first she hollowed the spine throughout, then she exasperated it with many processes both acute and transuerse, thereby as it were flanking the bulwarke against all annoyanc. The cavity is large, the better to containe the Marrow, in which respect the whole Spine is called *σπονδυλός*, the *Sacred Pipe*, by *Herophilus* the Canale. The Spine therefore is bony, not made of one but of many compacted together, as wel to helpe the variety of motions because it was fit the creature should moue forward and backward, as also to preuent danger; for the luxation, saith *Hippocrates*, of one Rack-bone is more dangerous then of many, because it constraineth the Marrow into an acute angle, and so doth necessarily either breake it or compresse it very sore.

Why made of
many bones.

These bones that make the Spine are called *σπονδυλοι*, from the similitude they haue with the whirle of a wheele. They are also called *vertebrae*, because by them the body is turned into diuers parts. *Pliny* calls them *ossa orbiculata* round or *Nut-bones*. This Spine is the *Basis* and foundation of the whole building, and therefore the ancients compared it to the carkasse of a Ship, for as the crooked ribbes and elbowes of a Ship are fastned to the bulke, and afterward the prow and the sterne or fore-castle are annexed, right so the ribs, the Armes, and the Legs are fastned to the Spine.

The figure of
them.

The figure of the Spine *Hippocrates* first elegantly expressed in the third Section of his Booke *de articulis*, and in his Booke *de natura ossium*, where he saith it is *ῥησχαλός*, that is, after a manner direct or straight; yet so that it inclineth sometime backward sometime inward. From the first Rack-bone of the Necke vnto the seuenth it inclineth inward that it might support the Gullet and the rough artery. From the first Racke of the Backe vnto the twelfth it beareth outward, to leane more space for the organs of Respiration, that is, for the Heart and the Lungs. The Loynes incline inward to support the descending trunks

trunkes of the hollow veine and the great artery. The holy-bone protuberateth outward with a kinde of rectitude or streightnesse to make the capacity of the *Hypogastrium* or water-course better able to containe the bladder, the right gut and the wombe.

We also will adde, saith *Laurentius*, that the fore and inner part is equall that it might not offend the bowels, yet scored throughout with transverse inscriptions: the backside is vnequall for the better insertion of muscles, and the safer egress of the vessels.

The Spine may bee deuided into foure parts, the Necke, the Backe, the Loines, and the Holy-bone. The Rackes of the necke are seuen, of the backe twelue, of the Loines sine, whose articulation and coalition is strange and wonderfull. The articulation is double, forward and backward; forward articulation is made by the bodies of the Spondels, and is more strict and close: the backward or hinder articulation is made by the oblique processes and is more lax or remisse, partly that the creature might moue more easily forward, partly least in bending backward the vessels should be distended, compressed, or broken. In a word, there are fixe articulations of the rackbones, two by their bodies, and foure by their oblique processes ascending and descending. That articulation which is made by the processes belongeth to *Ginglymos*, for euery racke (excepting the first and the eleuenth) receiuerh an vpper and is receiued by a lower, so that for the making of the *Ginglymos* there must be three rackebones.

The *Symphysis* or coalition of the Rack-bones is not *Gristle bound*, although their extremities be lined ouer with a gristle, but by Ligaments and those very strong, arising from the bones, from the gristles, and from the membranes that inuest the bones.

TABVLA XII.

See this Tables description, in fol. 771.

All the racke-bones of the Spine haue many things in common. First euery racke hath his body seated on the inside thicker and more fungous then the rest of the bone, to which also Appendices do grow and gristles. It is broad both in the vpper and in the lower basis to make the articulation more secure least it should lux sideward. Againe, euery rack hath a large hole wherein the marrow is contained, and this perforation is in all the rackes equall, saith *Laurentius*; for hee neuer could obserue it larger above or narrower below, although some haue thought the contrary. But, saith *Laurentius*, although the wonderfull fruitfulness of the marrow of the backe in propagating Nerues be by degrees diminished, yet those lower cauities are filled vp with thicker Membranes, prepared more straitly to vnite the thicker bodies of the Spondels. Thirdly, in euery rackbone there are three kinds of processes, oblique, transverse and acute. The oblique are foure, two in the vpper part and as many in the lower; the vpper ascending, the lower descending,

and by these are the Hinges of the backe hung together, for the articulation is made by *Ginglymos*.

The transverse processes are two, made to secure their muscles and for their originalls and insertions. The acute processe is single, seated in the backpart, and giueth the name vnto

Foure parts of the Spine.

The Articulation of the Rackes.

What the rack bones haue in common.

into the whole, for it is called *Spina*, or the *Spine*, and this is wanting onely in the first Racke.

Fourthly, in euery Rack-bone there are five Appendices, two in the body, two in the transuerse processes, and one in the Spine.

Finally, euery spondell which is articulated with another, hath a perforation which affordeth an outlet for the nerves, produced from the Marrow. Notwithstanding this perforation is not after the same manner in all the Racks, for in those of the Necke the lower is deeper then the vpper: in the spondels of the Backe, the semicircle of the vpper and the lower is equall: in the *vertebra* of the Loynes the whole cavity almost is formed by the vpper. And these things are common to all the Rack-bones. Now in their particular history we shall see what is proper to euery one of them; but first you shall haue a Table or two to shew you all the Rack-bones of the Spine from the top to the bottome, as the twelfth and the foureteenth.

CHAP. XI.

Of the Rack-bones of the Necke.

THe vse of the whole Neck and his admirable structure doth not belong to this place, and of it we haue spoken before: here we haue to do onely with the Bones, which are commonly seuen [*ta. 13, fig. 2, 3, 4*] differing both amongst themselves and from the other Racks of the Spine.

The two first are ioyned to the nowle by Ligaments, whereby the head is strongly fastned to the necke. The first of these [*ta. 13, fig. 2, 3, 4, FF ta. 14, fig. 2, 3, 4*] is called *Atlas*, because as he was imagined to hold Heauen vpon his shoulders, so this especially beareth h vp the Head. The body of it is more slender but faster then the rest, and it wanteth his vpper processe or

TABVLA. XIII.

See this description lib. 6. fol. 397,

his Spine, least it should haue hurt two small Muscles of the head: but ascending and descending processes it hath like the other Racke-bones, which in this are hollowed on either hand [*table 14, fig. 2, 2.EF*] Aboue to receiue two processes [*table 13, fig. 1, B C*] of the nowle-bone to helpe the motion of the head (*Galen* thought) in compasse, but *Columbus* reprobeth him who saith that by this articulation the head is inclined and reclined, that is, moued forward and backward. Below it receiueth the processes of the second Rack-bone. [*tab. 14, fig. 5, and 6, MM*] It hath also at the sides two transuerse processes [*tabl. 13, fig. 2, 3, II* *tab. 14, fig. 3, 4 GG*] perforated [*tab. 13, fig. 2, K* *tab. 14, fig. 2, H* sheweth the hole] for the ascent of a veine and an artery into the brane.

It hath also a *sinus* or bosome [*ta. 14, fig. 2, 3, B*] crusted ouer with a gristle [*fig. 3, 4, E*] the better to receiue the tooth [*fig. 7, O*] of the second racke,

Seuen Rackes
of the Necke.
I. Atlas.

The first Racke, and at the processes where the racks are ioyned there is a sinus on either hand: in the first [fig. 4, Z] and the second [fig. 6, r] bearing the forme of a rift or cleft, in the other racks it is orbicular, saving that in the chest it is somewhat long. Through these sinus are conveyed coniugations of sinewes and branches of Veynes and Arteries, ministering nourishment to the marrow and to the bones.

The second Racke [tab. 13, fig. 2, 3, N tab. 14, fig. 5, 6, 7] besides his body, his laterall processes [tab. 14, fig. 5, 6, 7 b] short and perforated with an oblique hole, [fig. 7, c] his Posterior proccesse byfurcated in respect of the muscles, [fig. 5, 6, 7 a] his ascending processes lightly bunching out, and his descending [tab. 13, fig. 2, K, tab. 14, fig. 6, 7 d] lightly sinuated: beside all these, I say, there yssueth out of the middle of his body an appendix (commonly called a proccesse) round and long, [tab. 13, fig. 2, 3, 4 O, tab. 14, fig. 6, Q, fig. 7 O] which because it is like the Dog-tooth of a man, is called the Tooth. Hippocrates calleth the whole Racke the tooth, and in the luxation thereof, saith he, happeneth the most incurable Squinsery. This Appendix is somewhat rough in the surface, that from thence a Ligament might yssue [table 13, fig. 5, f] by which it is fastened to the Nowle; about it also is cast a solid and round [tab. 13, fig. 5, K] ligament to keepe the marrow from compression. More over this second racke is ioyned to the first by a broad Ligament [tab. 14, fig. 5, F] which is orbicularly cast round about it.

TABVLA. XIII.

See this Tables description, in lib. 6, fol. 398.

FIG. I

The third Racke-bone [tab. 13, fig. 2, 3, SS, tab. 14, fig. 8, and 9] is called *axis*. It is ioyned most strictly and exceeding firmly on the outside to the other 2. The third, as also the three following, have their laterall processes byfurcated, [tab. 13, fig. 2, V, V, fig. 4 b] for the better implantation of the Muscles; but the sequent [tab. 13, fig. 1, 2, 3, 4, cha. 7] agreeth with the racks of the Chests, and his posterior proccesse is not alwayes byfurcated [tab. 13, fig. 24, X] but whole and sound: his body below is plaine, that it might equally be ioyned to that which followeth. Finally, all the racks of the necke excepting the first have Appendices, betwixt which doe runne thicke and soft Gristles for their more facile motion. And so much shal suffice to haue spoken of the rack-bones of the necke; for concerning the motions of the head, we haue spoken before in the Booke of Muscles.

CHAP. XXII.

Of the Racks of the Backe and the Loynes and the Holy-bone.

The backe is called in Greeke *πλάγος*, in Latine *tergum*, it consisteth of twelue racke-bones, [tab. 14, fig. 1 at D] iust so many as there are ribs on a side, for to euery rack-bone are two ribs [tab. 15, fig. 5, D P] articulated. The bodies of these Racks as also their processes do differ somewhat from the bodies and processes of the racks of the Necke. The bodies of the racks of the necke are long, broad and equall, that vpon them the Gullet and the Rough Artery might leane more securely.

How the racks of the necke and the backe differ,

The

The bodies of the rack-bones of the backe are round, convex or embowed, thicker also and not so solid. The spinall processes of the necke are byfuted, those of the backe are long, simple and do bend downward. The transuerse processes of the necke are broad and perforated. Of the backe, thick, solid and round, to make the articulation of the ribs more firme, excepting the eleventh and the twelfth, to which the last and the shortest ribs are fastned, that there might be more space left for the Liver, the Spleene, and the parts thereunder.

Of the twelve Rackbones of the backe, sometimes (but rarely) there is one wanting, more rarely is there one too many, yet for the most part dogs haue one more then men. They were made many for the better flexion of the spine, and are fastned together with strong ligaments, [tab. 14. fig. 1 RR. 14. 15. fig. 6 ch. 5] yet there is a good quantity of gristle betwixt each of them. [tab. 15. fig. 6. char. 1, 2]

The first.

The first racks of the backe is called by the Ancients *λοφία*, because it standeth out beyond the rest, the second is called *μωσχλησις*, that is, the Axillary spondell: the eight following *πλευρίται*, that is, *Costales* belonging to the ribs. The eleventh [tab. 15. fig. 3] is called *ἀππεμία*, because his spine is right, and this like a naile fasteneth the other racks. *Laurentius* addeth, that it is quite contrary to the first; for the first receiueh and is not received, this eleventh is received but doth not receive. The twelfth is called [tab. 15. fig. 4] *δισζωσις*, the compassing spondell.

Their figures.

These Racke-bones haue in the middle protuberating, round and embowed bodies, [tab. 15. fig. 1] above and below [tab. 15. fig. 1, 2, 3, 5, A] plaine, thicker then the Racks of the necke and lesse solid; full also of small perforations for the transportation of the vessels that carry the nourishment. Their spinall processes [tab. 15. figure 1, and 2, NOP] are long, simple and accure looking downward; the transuerse also [tab. 15. figure 1, 2, 3, 4, HI] (for the firmer articulation of the Ribs) are crasse, solid and long, determining into a round head.

TABVLA XV.

See this Tables description in Lib. 6. Fol. 393.

descend, and so the holes of the lower racke-bones become straiter. And so much of the backe.

The

They haue also two ascending processes [table 15. fig. 1. TV] and as many descending. [tab. 15. fig. 2, 3, 4b] The transuerse processes of the eleventh and twelfth racks [ta. 15. fig. 4. efgb] do differ from the processes of the other spondels, which variety *Galen* attributed to the tenth racke, for in a Dog or an Ape the tenth is the middlemost, but in a Man the twelfth.

They haue also five Appendices, two at their bodies above [ta. 15. fi. 3, 4] and below; two at the transuerse processes, and one at the extremity of each spine. They haue also two sinus or bosomes; [tab. 15. fi. 1 from C to D] one at the sides, another in the Transuerse processes, both small and answerable to the heads of the ribs, for into them the ribs are articulated. The holes of these Rack-bones [ta. 15. fi. 2, 3, 4 G] are proportionable to the marrow which they containe, and though *Laurentius* will not agree thereto, *Bauhine* conceiueh that the marrow is attenuated in the

The Loynes make the third part of the spine, and doe consist of five Spondels [ta. 16, fig. 12, from b to c] the greatest and thickest of all the rest which are fastned by Gristles and thicke Ligaments; above, with the racks of the Chest or the backe, [tab. 16, fig. 2, a, sheweth the last racke of the backe] below, with the Holy-bone, [tab. 16, fig. 1 and 2 c] for they lye vpon them, and are articulated by the interposition of a Ligamentall gristle; yet so, that the motion of the Loynes is more lax and dissolute then that of the backe: the Reason was, because wee might better incline our selues vnto the earth.

The first Racke of the Loynes is called *νεφρίτις*, from the Kidney which resteth it selfe vpon it. The last is called by some *ασφαλής*, that is, the supporter or the strengthner.

The Rackes of the Loynes, beside their laterall perforations made for the transmission of the Nerves, are also thrilled through with small holes.

Their processes are Ascending. [tab. 16, fig. 4, and 5] Descending [fig. 4, N] and transuerse, [fig. 2 cc ff. 3, 4, 5] longer and slenderer then in the rest: but their acute processes which they call the Spine [tab. 16, ff. 3, 4, 5 C D] are thicker then in the rest and broader, that to them the Ligaments and muscles of the backe might be fastened. The Spondels also of the Loynes (saith *Laurentius*) haue processes like a Medlar stone, which is found sometimes in them all, sometimes onely in the vppermost. And so much of the Loynes.

The Holy-bone, called *Os sacrum* and *ισχυν*, not because it containeth in it any sacred and hidden mystery, as some haue fondly imagined, but because of his greatnesse, for it

Table 16, figure 1, sheweth the anterior part of the bones of the lower belly.

Fig. 2. The posterior part.

Fig. 3, 4 and 5, do shew one of the Rackbones of the Loynes.

The third figure his fore-part, the fourth Figure his backpart, the fifth figure his side.

TABVLA XVI.

other side. O, 4, 5. The head of that descending proceffe.

is the greatest of all the bones of the Spine: So *Homer* calleth great Fishes *Pisces sacros*; and *Hippocrates* for the same reason calleth this Holy-bone *vertebram magnam* the Great racke-

2. The last rack-bone of the spine. From b to c 1, 2. The five rackbones of the Loynes or of the Rheynes. From c to d, 1, 2. The broad Holy-bone. d 1, 2. The hip bone or the *Coccyx*.

ee 1, 2. The laterall processes.

f, 2. His posterior proceffe or the Spine.

g, 2. The vpper proceffe.

h, 2, the lower.

ii, 1, 2. The plainer or bunching part of the *Coxa*.

k, 2, His lowest proceffe.

ll, 1, 2. A bosome or cavity in the lower part of that bone.

mm 1, 2. The hanchbone called *Os Ilium* and *Lumbare*.

nn 1, 2, the sharebone *Os pubis*.

qq. 1, the hole of the share-bone.

AA. 3, 4, 5. The vpper appendix of the body of the racke.

B, 3, 4. The lower Appendix.

C, 3, 4, 5. The vpper part of the spine of the racke of the Loynes, or a broad and rough line.

D, 5 the lower seat of this spine or the lower line.

E 5, A sinus or cavity at the side of the line D.

F, G, 4, 5. The appendix of the spine resembling a triangle.

H 3, 4, 5. A transuerse proceffe on either side.

I, 4. The right ascending proceffe.

K, A sinus of the left ascending proceffe.

L, M, 4, 5. the browes of this sinus before and behinde.

N 4. The descending proceffe of the

rack-bone. It is also called *man*, the broad bone. The figure of it is almost triangular, having a broad beginning, and ending by degrees into a narrowness. Immoveable it is and maketh the *Basis* of the backe. *Galen* saith it consisteth of three bones, by which he vnderstandeth the three first, but the truth is, that it is made of five bones [tab. 16, fig. 1. and 2, from c to d tab. 17, fig. 6, from A to F] as it were of proper racks knit and fastned together by gristles, which in growne bodies are so fast glewed that it seemeth to be but one bone, whereas in children the gristles betwixt the bones are very euident.

This Holy-bone on the foreside is hollow, smooth and equall: behind it is incurved or gibbous, rough also because of the Ligaments and the muscles of the backe. His acute processes are very small, the transuerse [tab. 17, fig. 6, and 7, K] but obscure, and determining into a cavity shallow, vnequall and rough, which receive the hanch-bones ascending processes, onely the first racke of the Holybone is allowed [tab. 17, fig. 6, 7, S] by which it is articulated with the descending processes of the last spondels of the Loynes. In the sides of the three vpper bones there are certaine *Sinns* or bosses insculped, to which the hanch-bones doe so cleave and are articulated [tab. 17, fig. 7, M] that they seeme to grow together.

It hath also Spines [tab. 17, fig. 7, dddd] looking downward, which in the fift and sixt bones are diuided into two parts. The perforations of this Holy-bone [tab. 17, fig. 6, and 7. char. 1, 2, 3, 4, 5, 6, shew the holes of the nerues; fig. 7, efgbik shew the holes for the marrow] are before and behind, not on the sides as in the other Rack-bones, because the hanches do occupy them, and the anterior are greater then the posterior, because greater nerues are distributed in to the foreparts and into the hind parts.

At the end of the Holy-bone appeareth the Rump-bone called *Os Coccygi*, [table. 16.

TABVLA XVII.

Table 17. Fig. 6, sheweth the fore-side of the Holy-bone and the Rump. Fig. 7, the back-side. Fig. 8, the Rump-bone of a man curved forward. Fig. 9, the Rump-bone of a woman curved backward. Fig. 10, sheweth the fore-side of the Holy and Rump-bones of an Ape. Fig. 11, their back-side.

From A to F 6. The fixe parts of the Holy bone placed vnder the fift racke of the Loynes.

From G to K 6, 8, foure bones of the Coccyx or rumpe which cleave to the Holy bone.

LL 6, 7, The large transuerse processe of the second Holy-bone, for the rest as farre as R, are by degrees angustated or strayned.

M 7, an vnequal bone of the Holy bone to which the right hanch bone is ioyned.

N 7, the exterior part of this *sinus* which is the plainer.

O 7, a long protuberacion distinguishing this exterior *sinus* from the interior, noted with Φ .

Φ 7 the interior *sinus* vnequall.

P Q 7, the vpper and lower part of this *sinus*.

R 6, 7, a swelling of the transuerse processes whereto a ligament is ioyned.

S 6, 7, The ascending processe of the first bone. T 7, a *sinus* of the processe receiuing the head of the descending processe of the fift racke of the Loynes. V X 7, the browes of this *sinus* on either hand. Y 7, The connexion of the descending processes of the first bone, with the ascending processes of the second bone. Z 6, 7, the coniaction of the transuerse processes of the first and second bones. ab 7, the connexion of the Holy-bone with the Rump. bb 6, 7, 8, a gristly ligament coming between the loose connexion of the Rump bones. c 7, 8, a gristle growing to the end of the Rump bone, dddd 7, the spines of the Holy-bone. efgbik 7, Holes betwixt the distances of the spines made for the transmission of the spinal marrow. 1, 2, 3, 4, 5, 6, in fig. 6, and 7, holes through which the Nerues of the Holy-bone doe passe.

fig.

Fi. 1, and 2. d. 17. f. 8, and 9.] because it is like a Cuckoos beake. *Galen* calleth it an *Appendix*, and vnder that name vnderstood the three lower bones that belong to the Holy-bone.

This Rumppe consisteth of three or foure bones [*tab. 17. fig. 6. and 8. from G to K*] and two gristles. One where it is fastned but loosely to the Holy-bone [*tab. 17. fig. 6, and 7.*] that it might yeeld backward when the thicker excrements are auoyded, and when we sit downe, returne forward into his place. In men it is curued or bent more inward to sustaine the right gut, but in women outward, because of the necke of the wombe. The second gristle is at the very extremity or end of it, [*ta. 17. fig. 3, and 7. c*] sometimes also it is placed betwixt his first and second bones.

That this Rumppe-bone in the time of the birth is retracted or drawne backward, we doe no more doubt saith *Laurentius* then we thinke it impossible that at that time the sharebones should be disioyned. And thus haue we brought to an end the History of the Spine which we made the first part of the Trunke. Now we proceed vnto the Chest.

CHAP. XXIII.

Of the Bones of the Chest in generall.

HE second part of the Trunke is called *Thorax*, a word which signifieth to leape, for the heart therein contained is moved with perpetuall subsultation. Wherefore because it containeth so noble a bowell, so necessary for the maintenance of life, therefore Nature hath defended it with bones. But againe because in Respiration it must continually be distended and contracted, therefore it was made also partly fleshy. The fleshy part we haue described in his proper places, that is to say, in the sixt and tenth bookes. The bony part though we haue touched vpon before in the sixt booke, yet because it pertained properly to this place, we will attend it here more distriktly.

The Chest therefore is circumscribed or bounded out, aboue by the clauicles, below by the Brest blade. But more precisely his parts are *anterior* or *posterior* or *laterall*. The *anterior* part is called *σθηνον*, *Sternum* the Brest bone: the sides *πλευραι*, *coste* the Ribs: the *posterior* part *ρῶν*, *dorsum* the Backe, whose vpper sides are called *ωμωπλάται* and *πτερύγια*, the Wings or the Shoulder blades, and all these we will describe in their order.

The diuision
of the bones of
the Chest;

CHAP. XXIII.

Of the Clauicles or Colter Bones.

HE Cavicles are called by *Galen* *κλειςίδες*, because they close or shut vp the whole Chest, or because they conclude the Arme and the Necke. *Celsus* calleth the place *Inguhum a iungendo*, of coupling, because it couples the Brest bone with the Shoulder blade and the Arme, for these two bones are very like the yoke wherein two Oxen do draw together: but by the name *Inguhum* we commonly vnderstand the hollow place aboue the clauicles where they vse to sticke a Swine. These Clauicles Nature hath giuen to no other creature sauing to a Man, an Ape, a Squirrell, a Mouse and a Hedge-hog. There are two, one on each side, seated ouerthwart in the bottome of the necke and top of the brest-bone. Their figure is not streight, but at the *Inguhum* embowed outward, [*ta. 18. fi. 2, H*] on the inside they are concauous or as it were guttered. At the shoulder-blade on the contrary they are lightly hollowed on the outside, but on the inside conuex or embowed. [*ta. 18. fig. 1, 2, 3*] In men they are not so crooked as in Apes; and therefore are most like the Latine S, but in Apes more like the S. They were made hollow on the fore side where they regard the *Inguhum*, that the vessels which run vpward, that is to say, the *Inguhum* veines and the sleepey arteries might not be compressed; but especially because of the propagation of sinewes, which from the marrow of the backe run vnto the arme-holes. They haue in them a double semicircle for more strength, for if they had been simply semicircular being fistulated and spongy within, and but as it were crusted ouer with a thin bony scale, they might easily haue broken, yea and are notwithstanding. Though these bone be long, crasse and crooked, yet they are more crooked in men then in women, that the motion of a mans arme might be at better command; but in women [*ta. 18. fi. 4, R*] they are lesse curued and arise higher: hence it is that women are so awkward when they throw a stone or strike a bal, but nature made recompence, for her neck is so much the more beautifull and statelie built, because there is no such hollownesse in it as in a mans.

Their names;

Their figure;

How they
differ in men
and women.
Their protuberations;

Rrrr

They

They bunch something forward, and haue two rising lines in them [tab. 18. fig. 1, 3, E fig. 2 FG] from which the *subclavian* muscle and a part of the pectorall muscle doe arise. They haue also a knob or protuberation from whence ariseth a Ligament which goeth to the inner proceffe of the shoulder-blade, [tab. 18. fig. 3, it ariseth about N] Neere their ends they are also on both sides exasperated, and from that roughnesse proceede Ligaments, and the muscle called *Mastoides* or the seventh of the head. But where the Clavicle is broad, there it affoordeth an originall to the muscle *Deltoids*, and an insertion to the second muscle of the bladder.

These Coller-bones fasten on both hands the shoulder blades with the brest-bone by *articulation*, yet there commeth betwixt them a large gristle [tab. 18. fig. 5 ST] which is moistened with an Oyly humor. And this gristle is called *κατακλῆς*, *clausura*, because it closeth them together, yet doth it not grow vnder them, but is onely held downe by the Ligaments that compasseth the ioynt, that in the motions of the arme and the shoulder it might giue a little way.

TABVLA. XVIII.

See this Tables description in lib. 6. fol. 393.

the opposite side: and when it is voluntarily bent or with violence moued that way, might yet be able to recouer it selfe, or to stay his fall; therefore the clauicles were set betwixt the two sides to inhibite or preuent any such ouer-extent or downe fall: againe, were it not for the Clauicles when we offer to thrust any thing strongly backe-ward, the blade would fall forward, as sometimes the arme falls vpon the ribs when it is luxed or put out of ioynt, or when the blade hangs downe like a wing, as it will do when the Coller-bone is broken. And thus much concerning the Clauicles.

It hath two heads, one smaller, cruisted over with a gristle, [tab. 18. fig. 1, 2, 3, 4] whereby it is ioynted to the brest-bone as we said: the other is broad and somewhat long [ta. 18. fig. 1, 2, 3, 2] by which it is articulated to the vpper proceffe of the shoulder-blade by the interposition of a peculiar gristle, which *Galen* calleth the small gristly bone, made, saith he, for the security of the ioynt.

The vse of the Coller-bone is, that the Blade should not together with the Arme fall vpon the breast, and so many motions of the arme bee forfeited. It is true indeed that these bones may seeme not to belong vnto the Chest, because all brute beasts haue Chests, but very few of them these bones. We answer, that Nature is most Wise in her administrations and hath therefore giuen these bones vnto men because they haue hands, which it concerned them much diuersly to moue into many positions from one side to another. Now because in such flexions the arme should not fall hedlong as it were into

CHAP. XXV.
Of the Brest bone.

The Brest-bone is the forepart of the Chest, and called in Greeke *σέπρον*, either because [ta. 18, fig. 9, g h i] it is disposed in the middle of the ribs, or because there is *σέπρον τῆς ψῆς*, *Mentis firmitas*, because the heart lyeth vnder it. Hippocrates calleth it *σῆθρον*, the Latines *Pectus* or *os pectoris*, the brest bone, because it maketh the forepart of the brest, and safeguardeth the noble parts therein contained. This Brest-bone is somewhat conuexe or embowed, long also or broad, and because it is like the handle of a dagger such as was vsed in old time, it is called *εὐποειδής*. The substance of this bone is not solid as other Bones are but fungous and reddish, compounded also of Bones and Gristles; for it is not one bone, vnlesse it be in very old men, otherwise if you scrape off the membranes, you may see it is compacted of many. In Infants new borne it is altogether gristly excepting the first bone of it, a little after there may be obserued eight distinct parts, each of them distinguished from other by a large and thicke Gristle, seuen of which were made to receiue the articulation of the seuen true ribs. The eight was framed to be a foundation to the Sword-like Cartilage, which we properly call the Brest-blade.

These bones after seuen yeares are conioyned and begin to grow fewer, yet sometimes foure may be distinguished, that is to say, the first [ta. 18, fig. 6 a] which is the broadest, the second and the last: those betwixt these do grow into one; but in growne bodies there are but three, distinguished each from other by a transuerse line. The first and the last both in young and old are alwayes one, but the middlemost is distinguished into many parts, according to the youth and age of the party, which parts are *gristle-bound* or fastened together with a gristle betwixt them by *Coalition*. For although according to the motion of the chest it seeme to be eleuated and againe depressed by the helpe of the ribs, yet it hath no motion apart or by it selfe. In dogs it consisteth alwayes of seuen Bones ioyned together by *Synarthrosis* or *Coarticulation*. But we will follow the description as it is in a man, in whom the Bones are three.

The vppermost [ta. 18, fig. 6 abc] is larger and thicker then the rest, and is like the head or pummell of the handle of a dagger, but flat and vnequall; horned or crescent about [ta. 18, fig. 9, g] which maketh a kinde of cavity or den which some haue called *Iugulum*. In the midst for more strength it protuberateth like a triangle [ta. 18, fig. 6, a] at which the first ribbe [fig. 6 g] is ioyned; a gristle comming betwixt them. A second gristle it hath, where the first bone is ioyned to the second. [ta. 18, fig. 6 b] On the inside about the midst it hath a bosome grauen in it [ta. 18, fig. 7, d] made to giue way to the descent of the rough Artery, and other bosomes on each side [ta. 18, fig. 6 and 7 e f] which receive the heads of the collar bones.

The second Bone of the *Sternum* hath on either hand in the sides many cavities [ta. 18, fig. 6 klmn] distant one from another vnequally, & it is compared not amisse to the haft of a dagger wherein there are inequalities for the fingers to take fast hold vpon, for euen so these impressions do receiue the gristles of the third, fourth, fift and sixt ribs. This Bone is narrower then the other two, and in women sometimes toward the end perforated with a broad hole much like a heart, [ta. 18, fig. 8 u]

The third Bone is lesse but broader then the second [ta. 18, fig. 6, and 7 f] wherefore *Celsus* wrote that the Brest-bone was horned or crescent at both ends; but you must vnderstand him of a man and not of a dog. Hereto is ioyned the gristle of the seuenth rib iust where it selfe is fastened vnto the second bone, and in some bodies it is diuided in the midst by a line.

On both sides this *Sternum* is smooth, sauing that about it is somewhat exasperated to giue an originall vnto the muscle *Mastoides* or the seuenth muscle of the head. Gristles it hath, (beside the two vpper which goe betweene the coniunction of it with the Clauicles) one betwixt the first and the second bone [tab. 18, fig. 6, 7 b] which supplieth the place or doth the office of a Ligament. Another in the end, long, moueable, and triangular [table 18, fig. 6 and 7, e] which commonly is sharpned like the poynt of a sword, whence it is called *εὐποειδής*, *Ensiformis* and *Mucronata*, the *Blade of the Brest*; this also is sometime broad in the end, sometime byfurcated, and therefore some haue called it *Furcella*, the *little forke*. Oftentimes it is round, sometimes double, saith *Laurentius*, and the lesser part lyeth vpon the greater, as the leaues of the Herbe called *Horsetounge*: sometime also it is perforated

ted [tab. 18, p. 8 u] to transmit the Mammary veines which are accompanied with a nerue. If this gristle (saith *Platerus*, and *Baehne* consenteth with him) be too much pressed or curued inward in children, which disease women call the *Compression of the Heart*, it offendeth the Liuer and the stomacke vnder it, and those children dye of that kinde of consumption which we call an *Atrophie*, for in children this gristle is somewhat long, and oftentimes may be felt with the finger. Heere also we must obserue that cavity which the Ancients call *xapdia*, commonly the *Heart-spoone*. The whole brest in men is somewhat eleuated or raised vp, but in women it is more flat and depressed because they haue greater dugs which would stand out too far if the brestbone were raised as high as it is in men.

The vse of the brest bone is the same which we shall say anon the vse of the ribs is. The Brest-blade is a defence to the parts thereunder, that is, the Midriffe and the mouth of the Stomacke; and this may be proued, saith *Baehne*, because if it be compressed or rubbed too much, a *Nausea* or loathing will follow: againe, he that is ready to vomit shall finde a paine iust vnder it. And thus much of the Brest-bone.

CHAP. XXVI.

Of the Ribs.

The Names
and Number.

THE sides of the Chest are called by the Grecians *μεσος*, and *σώμα*, because they are placed side by side like the Rowers in a Galley: the Latines call them *Costae*, we call them the Ribs. They are commonly both in Men & in women on each side twelue, oftner more then fewer. For nature would rather there should be abundance then want. And in a publicke Anatomy when a Malefactor was cut vp, *Baehne* found thirteen on each side: the first on the left side was perfect, but the first on the right side was imperfect.

The true ribs.

Falopius also twice found one too many, *Columbus* once eleuen at *Padua*. They are diuided in to True and Bastard Ribs. The true Ribs are the seven vppermost [ta. 18, fig. 9, from char. 1 to 8] so called, because they make a perfect circle being ioyned together by the Spondels of the Back and the Brest-bone. For behind they are fastened with strong Ligaments by *Dearticulation* or *Diarthrosis* to the Spondels of the backe. [ta. 18, fig. 10, ST] And that they might sticke the closer the knot is double, one higher at the body of the Spondell, another lower at his laterall process: Before, they are articulated to the brest-bone, [ta. 18, fi. 9, c] for their Cartilages be like little heads ioyning with the smooth bosomes of the *sternon* by *Synarthrosis* or coarticulation. The two first Ribs are called *ἀντιστοιχοί*, as it were *Retorted*, the two next are called *σπερδι*, that is, *solid*; the three last, by *Pollux* (he that gaue them all Names) *σπεινιδες*, that is, *Pectorall* Ribs.

The bastard ribs.

The Bastard Ribs are the five lower; they are soft and almost gristly, that themselves might be more safe from iniuries, and by them the parts thereunder. And indeed, the prominent parts of bones were for the most part by Nature made gristles, for a gristle if it be wounded or violated will not breake but easily reunite. These Bastard ribs therefore do end into exquisite gristles, which are retorted vpperward and fastned one to another [ta. 18, fig. 19 FF] excepting the twelfth, and so are ioyned to the gristles of the true ribs; [ta. 18, fi. 19, I]

They may also be said to be imperfect, because they are onely articulated vnto the Racke-bones, but that after diuers manners. For the eight and the ninth haue a double articulation, yet doe their ioynts not sticke out so farre as the ioynts of the true Ribs doe, which receiue more strength from the Rack-bones then from the Brest-bone. The eleuenth and the twelfth haue onely the vpper articulation, as also hath the first oftentimes, but the tenth is ioyned sometimes with a double ioynt, sometimes with a single.

These Bastard ribs do not attaine vnto the Brest-bone, that the lower belly might better be dilated when the stomacke is well stuffed or the wombe impregnated. The eleuenth sometimes, sometime also the twelfth are fastned to the Midriffe. Againe, the twelfth is the least of them all (and according to some mens estimation doth not deserue the name of a rib) that there might be roome left for the bowels in the lower belly, and because it was so little *Galen* calleth the eleuenth Rib the last. Sometime this twelfth Rib groweth to the oblique muscle of the *Abdomen*, sometime againe it is seen to haue a circumscription of a proper muscle whereby it is drawne downward.

All these ribs are not onely of a bony yet fungous substance, [table 18, figure 11, R] but also

also euery one hath his owne Gristles, both behind where they are articulated vnto the Rack-bones, and before where they are committed to the brest-bone, [ta. 18, fi. 9, AB shew the con-
iunction of the ribs with the gristles, C D. the coniunction of the Gristles with the brest-bone] But
the fore-gristles are greater and thicker, because the fore-part of the chest is distended and
contracted: so likewise the gristles of the bastard ribs are longer then those of the true ribs,
but the gristles of the true ribs are harder then those of the bastard ribs, because they were to
be ioyned with the brest-bone which is a harder substance, whereas the gristles of the bastard
ribs are thinne and narrow, because they are ioyned with other Gristles: and hence it is that
some Anatomists haue called them *χυδρος*, that is Gristles. Notwithstanding the Gristles of the
first and last ribs are very short, but that of the last is narrow and sharpe, that of the first broad
and large. The lower ribs in men remaine gristly euen to extreame old age; the vpper some-
what before that time do begin to grow bony, and haue, as we may say safely by *Galens* war-
rant, bony gristles. In Virgins after their paps begin to swell the gristles also grow somewhat
bony, the better to sustaine the waight of the paps that lye vpon them, whereby if the ribs
should be depressed, the motions of the Chest would be interrupted.

The figure of the ribs is semicircular like a Bow when it is drawne, to make the figure of the chest circular and round, whereby it becommeth stronger and more capacious. The length
of the ribs is not the same in them all, for the vpper & the lower are the shortest, the middle-
most are the longest and the broadest, excepting the first which is the broadest and shortest of
all the rest. Againe, the vpper ribs are more crooked and rounder bent, the lower are not so
embowed. All of them in their originall are narrow and somewhat round, and by how much
they come neerer to the brest by so much do they grow the broader, which broader part is
called *πλάτη*, or the Palme, the narrow part which is towards the spine *σπονδυλ*, the Rower.

They are also thicker aboue then below. On the outside especially where they are tyed to
the racke-bones they are rough [ta. 11, fig. 11 P] and vnequall, that from thence the Liga-
ments might proccede by which they are fastned to the Racks; in that place also they haue
two protuberations, one whereby [ta. 18, fi. 11, L] they are articulated to the sinus or bosome
of the Rack-bone, another where they are ioyned to the transuerse processe. [ta. 18, fi. 11, M]
They are also exasperated [ta. 11, fi. 11 Q] to receiue that Muscle of the Chest which is called
Sacrolumbus, accounted by *Vesalius* and *Falopius* for the fourth, by *Columbus* the fift Muscle
of the chest, as also for the originalls and insertions of the intercostall muscles. On the insides
they are smoothe, that they might not hurt the *Pleura*, and in the lower part of euery rib, [tab.
18, fig. 11 K] there runneth a sinus like a canale throughout their length to receiue three Ves-
sels, a Veine, an Artery and a Nerue, but the Nerue lyeth next vnto the ribbe: and these
sinus are most conspicuous in the middle of the Ribs, and in that part that is next to the Racke-
bones.

The vse of the ribs is to be a defence vnto the brest, that is, to defend the bowels therein
contained. Moreouer, to yeeld a fit place for the implantation and supportation of the Muscles
which serue for Respiration, that they should not fall downe and interrupt the functions of
the Heart and the Lungs. Wherefore, that when we breath in and breath out (though we be
faste asleepe) the chest might more easily follow his necessary constriction and dilatation, a
part of them was made gristly, which gristles likewise defend the bowels seated vnder them,
and sustaine some Muscles of the *Abdomen* which otherwise would fall inward and impeach
the offices of the bowels of the lower belly. And thus much of the Ribs.

CHAP. XXVII.

Of the Shoulder-blades.

TH E backpart of the chest is called the Shoulder-blade, in Latine *Os Scapula*, in His names
Greeke *ωμοπλάτη*. [tab. 19, fig. 7, 8, 9] There are two of them, one on each side,
which behinde fitteth vpon the top of the Ribs like a shield for their defence, and
is articulated with the clauicle and with the arme; for whose sake it was especially
created, as well to hold it to the body, as to affoord an originall to many Muscles by which
it is moued. It is fastned also to the ribs, to the nowle and to the bone *Hyois* by the interposi-
tion or mediation of Muscles.

The figure of it is after a sort triangular; on the inside [tab. 9, fig. 7, M] concanous: on the
outside

outside: [ta. 19. fig. 8, V, F] it is prominent, which place is called the Basis, and this basis hath an angle [ta. 19. fi. 7, 8, 9] *shew the upper Angle* and a rib both above and below; from which is produced a spine that looketh upward. [ta. 19. fig. 8. and 9, GH]

Table 19. Is the same with Table 16. a little before in folio 979.

The extremity of this Spine is commonly called *ἀκρόμιον*, albeit according to Hippocrates *Acromion* be the articulation of the clauicle with the vpper part of the blade or a gristly bone, which like a Ligament tyeth those Bones together.

Processes
three.

It hath three processes: the first is the shortest, and hath a short necke which is called *Scapula cervix*, [ta. 19. fi. 7, 8, CD] which Necke endeth into a sinuated or hollow *Cup* or head, [ta. 19. fig. 7 and 8 AB] which *Cup* receiveth the head of the arme, and it is compassed with a thicke gristle [ta. 19. fig. 8, K] whereby the *cup* is enlarged, that the head of the arme should not so easily fall out of ioynt. The second processe is the end of the spine, of which wee spake euen now, which hangeth ouer the ioynt of the arme, called therefore *Acromion*, [ta. 19. fig. 7, 8, 9 K] the point of the shoulder and the top of the shoulder, and by this processe the shoulder-blade is ioynd with the clauicle. The third processe is the least, and on the inside [ta. 19. fig. 7, and 8, E] which is called *σπυραιδης*, and from the likenesse it hath with an Anchor *ἀγκυραειδης*, Some call it *Coracoides*, because it is like the Beake of a Crow, and this processe holdeth the bone of the arme in his seat.

Appendices
five.

It hath five Appendices, three are at the inside and at the basis, and affoode an originall to some Muscles: [ta. 19. fi. 7, 8, 9 X] the other two do breed Ligaments which ioyne the arme to the head of the blade, and the clauicle to his second processe which we called *Acromion*.

Cavities
two.

It hath also two cavities, one above the Spine, and another below it, called *Interseapilum*. Finally, there is an inequality in this Bone, for in the middest it is very thin, in the processees thicke, medullous and fungous. It hath also perforations which admit Veines and Arteries for his nourishment. And thus much of the shoulder-blades.

CHAP. XXVIII.

Of the Hip, Hanch and Share-bones.

The third part of the Trunke was said to be the Bone without a name, so called first by *Oribasius*, some from the greater part called it the Hanch-bone: *Rufus*, *ἰσχυρὸς* *Coxa*. [ta. 20. fi. 12, 13, and 14] It appeareth to be one on each side, because the gristles are dried vp, but in children till the seventh yeare of their age it is found to be made of three Bones diuided by gristles, and therefore they are said commonly to be on each side three bones.

The Hanch
bones.

The vpper and broader parts which are ioynd with the Holy bone [ta. 20. fig. 13, ABCC DD] are called *ὀστέον ἰλίου*, in Latine *Ilium*, in English the Hanch-bone [ta. 16. fi. 1 mm, ta. 20. fi. 13, above T to f] Their semicircular circumference is called the Spine of the hanch-bone, [ta. 16. fig. 1 and 2, ii, ta. 20. fi. 13 HLMN] which is vnequall, that some muscles might take their originall therefrom, to wit, the oblique ascendent of the *Abdomen*, the fist of the chest, the first bender of the Leg, and the first extender called *Membranosus*. The inner part of the circumference is called *Costa* or the rib; the vtter part of the whole bone [ta. 20. fi. 14 at X] is called *Dorsum Ilii* the backe of the Hanch-bone, wherein there are vnequall inscriptions or lines for the three muscles of the Thigh which make the Buttocks.

The interior part is hollow and broad to affoord a fit and conuenient position to the internal Iliacke Muscles: [ta. 20. fig. 13 KK] above also it extuberateth for the Square muscle of the backe that is the first, and below for the tenth of the thigh.

The lower and vtter parts of this bone are called *ὀστέον κοξυδαις*, [ta. 16. fig. 1, nn. ta. 20. fi. 13, below T and f as far as to RP] in which there is a great sinus which they call *Acetabulum* and *Pixidem* [ta. 20. fi. 12 and 14 abc] the *Cup*, and properly in our English Tongue the Hip, to which the head of the thigh is articulated exceeding strongly. This *cup* or Hip hath a gristly processe, [ta. 20. fig. 12 and 14 e] called *Superoilium* or the brow, in whose circumference there are obserued three bosses, two protuberations. [ta. 20. fig. 12 and 13, T, V] an acute processe, [ta. 20. fig. 13 and 14 g] and finally an Appendix [ta. 20. fig. 13 and 14 i] that is very thicke; all these were ordained for the production partly of Ligaments, partly of muscles.

The Share-
bones.

Finally, the fore parts of this vnnamed Bone are called *ὀστέον ἰσχυρὸς*, *Pubis*, in English the Share-bones. [table 16, figure 1. and 2, pp, table 20, figure 13 and 14, that which is below R and e] because

Figure 12. sheweth the forepart of the Coxendix which is ioyned to the right side of the Holy-bone.

Fig. 13, the inside of the Coxendix. Fig. 14, his outside.

Fig. 15. the gristle that goeth betwixt the Share-bone in a man.

Fig. 16. the gristle that goeth betwixt them in a woman.

TABVLA XX.

From T to f in Fig. 13, and 14, A part of the Coxendix called *Osiolum* the hanch bone, that which is below as far as to R and ϕ is called by the name of Coxendix the Hip, the remainder is the Sharebone.

ABCCDD 13, the foreside of the hanch bone where it is ioyned to the Holy-bone distinguished by a protuberation CC into two *sinus* ABDD.

EFG 13, the backside of the hanch bone which gapeth fro the Holy bone, & is filled vp by a gristle.

H 13, 14, a part of the backside reaching out beyond the proccesse of the Holy bone.

K 13, An impression in the inside of the hanch-bone made for the originall of the fift muscle of the backe.

L 12, 13, the inside of the appendix of the hanchbone.

M 12, the anterior end of the appendix.

N 13, 14, his posterior end,

O 12, 14, the outside of this appendix.

PQRI 13, A swelling from whence the tenth muscle of the thigh issues.

x 13, this place affoordeth an originall to the 7. muscle of the thigh.

S 12, 13, 14, the vpper *sinus* of the Coxendix, above which do run the sixt muscle of the thigh, and the 7. with a Nerue.

T 12, 13, 14, A higher protuberation above this *sinus* or cauity V. 12, 13, 14, another lower protuberation. XYY 14, a darke line in the backe of the hanch bone X, another in the same place YY. Y 12, 13, the vpper *sinus* of the Sharebone a b 12, 13, The Cup of the Coxendix which admitteth the head of the Thigh, the deepe hollownesse of it is marked with c. d 14, the *sinus* or bosome wherein the Cup is grauen. e 12, 14, the brow of the Cup. f 13, 14, a cauity of the Coxendix made for transmission of the fourth nerue of the Leg. g 13, 14, the acute proccesse of the Coxendix. h 12, 13, 14, a *sinus* to which the tenth muscle of the thigh is reflected. i 12, 14, the Appendix of the Coxendix. k l m n 14, diuers impressions in this appendix. o 14, the posterior end of this Appendix. p 12, P 14, the roughnesse of the Share-bone to which the gristle groweth. q 12, 13, 14, the hole of the Share-bone. s 12, 13, 14, a bosome about the hole of the Share-bone. t 12, 13, 14, the lower proccesse of the Share-bone.

because in the middle of the share they are ioyned together by a gristle. [ta. 20. fig. 15, at 6] Before and above they have a *sinus* or bosome, [tab. 20, fig. 12, r] made for the descent of the crurall vessell: they are also rough for the originall of the right and pyramidall muscles of the Abdomen, and of the second bender of the Leg. But otherwise they are but thin bones and perforated with the greatest hole that is in the whole body [tab. 16, fig. 1, and 2, qq. tab. 20, fig. 12, 13, and 14, q] This hole was made for lightnesse, and the empty place is stopped vp on the outside with the externall *obturador* or compassing muscle of the thigh, and on the inside with the internall, vnder the hole it hath a proccesse [ta. 20, fig. 13, 14, t] from whence the bodies of the yard and some muscles take their originall.

These Bones ioyned with the Holy-bone doe make that cauity which they call the *Bason* Their vses. [tab. 16, fig. 1, sheweth it] which containeth a part of the Guts, the Bladder and the Wombe; and to conclude, these three bones put together make the *basis* or foundation of the body, which it selfe is immoueable whilst all the body moueth vpon it. And thus much of the Trunke.

CHAP. XXIX.

Of the Bones of the Arme and the Cubit.

WE haue gone through the two first parts of the *Skeleton*, that is, the Head and the Trunke; the third remaineth which comprehendeth the Ioynts. These Ioynts are two, the Hands and the Feete. The Hand we call all that which is betwixt the shoulder-blade and the Fingers; and is deuided into three parts, the Arme, the Cubit and the Hand properly so called, of which we will speake in their order, and then descend vnto the Foote.

The names of
the arme.

The Arme is called by the Greekes *βραχιον*, by *Celsus* *Humerus*, commonly *brachium*. It is but one bone [ta. 21, fi. 1 and 2] round and vnequal, long also and the greatest of all the bones of the hand, yea of the whole body except the Thigh-bone if we beleue *Galen*. But *Columbus* saith that it is not so bigge as the Holybone, nor so broad as the Hanch-bone, nor longer then the Leg-bone. It is articulated to the shoulder-blade and the cubit, and for these articulations both the ends of it are protuberated or swell into heads. For in the vpper part where it is inserted into the *Cup* of the Blade, and articulated by that kinde of *dearticulation* which we called *inarticulation*, it hath an Appendix [ta. 21, fi. 1, AEFH] which maketh the head of the Arme or the *Acromion* seated in the vpper but inner parts.

One bone.

The head is large and orbicular, and crufted ouer with a gristle [tab. 21, fi. 1, and 2, ABC] that it might be turned in all motions within the cauity of the *Cup* of the blade, which also is enlarged for that purpose with a plentiful gristle. At the outside of this head do bunch out two processes rough and vnequall, whereout doe arise the strong Ligaments which tye the Arme to the blade. The first of these is seated on the fore side [fig. 1, D] the other and the greater on the backside [fi. 1, and 2, E] and the greatest part of them both is contained in the Appendix.

Two sinus.

It hath two *Sinus* or bosomes, one orbicular and rough at the side of the head which it distinguisheth from the processes [ta. 21, fig. 1, FG] to which a Ligament is implanted. The other is on the outside and long, running downward [fi. 1, HI] betwixt the two processes which it doth distinguish or separate. And this *sinus* was grauen for the beginning of the bending muscle of the cubit which is called *Biceps*, and groweth out of the *cup* of the shoulder-blade, for through this *sinus* as through a pulley that muscle doth run.

The lower part of the Arme which at the Cubit is articulated to the Ell and the Wand, is in Infants increased by an Appendix, which in proceffe of time is so vnited to the bones that there remaineth no footstep, no remembrance of the appendix. This lower part is broad and the figure of it diuers, for it is partly protuberated and partly excauated or hollowed.

The processes.

The protuberations or processes are two very notable on each hand, and one at the sides of the orbe, because it was to be articulated to two bones. The exterior of these [tab. 21, fig. 1, P] is the thicker, and endeth into a head crufted ouer with a gristle which entereth into the vpper *sinus* or cauity of the Wand. It is situate before, and is made round to turne the Wand vpward and downward. This processe at the outside buncheth out very farre, that from hence some muscles might take their originall [fig. 1. vnder Q] and endeth into an vnequall Line. Betwixt the head and the protuberation there is a *sinus* on the backside [fig. 2, R] grauen, to conuay the fourth nerue that passeth vnto the hand.

The inner processe [S] which may easily be felt euen in liuing bodies, and swelleth much inward to yeild a place for the originall of some muscles, is likewise crufted ouer with a gristle. Neare the side of the orbe it hath two *sinus* or cauities, one shallow in the fore side [fig. 1, T] to leade along the third nerue that passeth vnto the Hand; the other in the backside [fig. 2, V] through which the fift nerue is conuayed. Betwixt these two *sinus* we meete with an orbe, which saith *Falopius* may by a curious Anatomist be called a third appendix. *Archangelus* calleth it a third and middle processe.

It is also called *trochlea* or the pulley whereto the Ell is articulated by *Gynghimos*, and it is mooued onely with a right motion: this orbe because it hath a cauity in the middest [K] and buncheth out on either side [LM] seemeth to be like the gutture of a pulley wherein the cord doth slip, and therefore it is commonly called *Humeri rotula* the gutture of the Arme. [KLM] That part of this cauity which is like a pulley was at the first an Appendix; yea betwixt the two processes there went a gristle which after the senenth yeare groweth bony, and maketh a part of the cauity and the outward browe thereof. In the vpper part

of

Table 21. sheweth the Bones of the arme and the Cubit.

Fig. 7 and 8. The inner and vtter scate of the left wand.

Fig. 9. The lower part of the left wand.

Fig. 10 and 11. The lower and vpper part of the right wand.

Fig. 12 & 13. The vpper & lower extremity of the right Ell.

TABVLA XXI.

A, B, C, 1, 2. The head of the arme which entreteth into the cavity of the shouderblade,

D 1, His anterior proceffe.

E 1, 2. the other posterior proceffe.

F G, 1, 2. the orbicular cavity of the head thereof.

H, I, 1, a right sinus leading directly downward.

K 1, 2. the sinus of the gutture of the arme which receieth the cubit.

L, M, 1, 2. the two lips of the gutture, the inner and the vtter.

N, I, 1, 2. the anterior sinus in the vpper part of the gutture.

O, 2, another posterior sinus.

P, I, 2. the head of the arme to which the wand is articulated.

Q 1, 2. a line swelling out in the vtter side of the arme.

R. 2. a bosome of the vtter proceffes of the arme.

S, 1, 2. the inner protuberation of the arme.

T 1, the anterior sinus of the inner protuberation.

V, 6, the posterior sinus of the same.

X, Z 2 the length of the arme betwixt his thicke ends.

Y 1, the middle part, where the bone of the arme is as it were written.

a 1, a bunching line in the fore-side, which runneth along as farre as to f.

b, c, 1. Impression on both sides the line.

d 1, the vpper gibbous part of the Arme.

e, 1, 2 a roughnesse in the outside of the middle of the arme.

f 1. another some what higher, but more inward.

Fig. 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13.

A 3, 4. the vpper part of the cubit, wheerby it is ioyned to the arme.

B, 3, 4. the lower part of the cubit reaching to the wrest.

C 3, 5. 13. the anterior and vpper proceffe of the Ell.

D, 3, 4, 5, 13. the posterior and vpper proceffe of the Ell.

E, 3, 4, 5, a sinus of the Ell, receiuing the pully of the arme.

F, 13, a protuberation in the foresaid sinus.

G, H, I, 13. the internall side depressed nere vnto the protuberation at G. the externall side at H.

I, 13, a sharpe small cauity in the left hand, to which the right answers on the other side.

L, 3, 5. 13. an asperity in the roote of the proceffe of the Ell.

M, 3, 4, 7, 8. 11. the Necke of the Wand.

O 11. a sinus of the Wand whereinto the head of the arme doth enter.

P 3, 4, 5, 6, 12. the necke of the Ell.

Q, 3, 4, 5, 6, 12. the appendix of the Ell.

R, 3, 4, 5, 6, 12 the proceffe of the Ell called *Styloides*. S 12, a sinus or cauity in the basis of the appendix of the Ell. T 3, 4, 7, 8, 9, 10, a Gristle growing to this sinus. V 4, 6, a sinus in the side of the appendix of the Ell. X, Y, Z, 4, 6 three corners of the latter proceffe of the Ell. aa 3, 4, a line or the first bunching part of the Ell. bb 3, 5, the second line of the Ell. * an oblique inferior line of the Ell. cc, 3, 4, 5. the sharpenesse of the Ell touching the wand. dd 3, 6 the first vtter side of the Ell. e 4, 6. the 2 vtter side. f 3, 5. the lower rough side. gg 4, 6, a line drawne in the vtter side. h, i, 1, 3, the commissure of the wand with the ell about h and below i. i, k, 3 A distance where these bones doe part asunder. l, 13, a sinus of the Ell wherein the head of the Wand is turned. m, 7, 8. 11 the head of the wand, resting vpon the sinus of the Ell. n, 3, 7, the lower appendix of the wand. o 9, a Sinus of the Radius receiuing the head of the Ell. p, 5, 12, the head of the Ell entering into the Sinus of the wand. q, 3, 4, 7, 8. 11. a roughnesse swelling vnder the necke of the wand. rr, 3, 4, 7, 8. an acute line respecting the Ell and the wand. s, 3, 7, the rough internall side of the Wand. tt, 4, 8 the smooth externall side of the wand. u, 4, 7, 8. a roughnesse in the midst of the length of the wand. x y 3, 10. a Sinus of the wand wherevnto the wrest is ioyned. z 3, 10, a protuberation in the midst of the Sinus. a 3, 7, 8, 9, 10, the proceffe of the Sinus. b, 4, 8, the inner Sinus of the wand double which carieth the tendons. c 4, 8, the externall double Sinus of the Wand. d 4, 8, the fourth Sinus producing a Ligament. e 4, a Sinus of the wand common with the Ell.

of the Orbe there are grauen two cauities or bosomes, which *Hippocrates* called *βαβυιδες*, distinguished onely by a scale: one of these is in the forepart, [figure 1, N] the other which is the larger and the deeper [figure 2, O] is in the backpart, and these two are the limites of the motion of the Ell. Moreover this bone throughout his length is round in the midst, [figure 1, b] in the sides a little compressed, [figure 2, a c] behind yet more depressed, wherein there is a shallow gutture [fig. 2 R] whereunto the fourth Nerue of the arme creepeth; before, there is a double asperity or roughnesse, one [figure 12, c] made for the stronger implantation of the muscles that moue the arme, and for the originall of the muscle which is called *Brachieus*. In old men the roughnesse is so great that from thence there seemeth a proceffe to grow, whereunto the muscle called *Deltoides* is inserted. The other *Asperitie*, [figure 1, f] is that whereto the fleshy part of the Double-headed Muscle doth grow.

Perforations. It hath also small perforations nere the browes of the head and the bosomes, through which some Ligaments are produced or implanted; and moreover some other perforations it hath on the inside of the length of the bones which admit certaine veines. Finally, the bone of the arme is on the inside hollowed with a deepe bosome or cauity, as well to containe the Marrow which is his Nourishment, as also to make the Bone the lighter.

The Cubite. The second part of the hand in the large acceptation is called the Cubit, and is seated betwixt the Arme and the wrest, with both which it is articulated. It consisteth of two bones lying one vpon another, and fastened together with a Membranous Ligament. These bones are long, but yet shorter then the bone of the arme, and they haue appendices at either ends.

The Ell. The lower of these [fig. 3, 4 AB 5 6] which is also the greater, hath for the most part the name of the whole and is called *Cubitus*, yet to put a difference it is also called *Vlna* the Ell, and sometime *foeile manus*, and is articulated to the sinus [figure 2, KLM] which is in the gutture of the arme by *Ginglymos*, and by this articulation both flexion and extention is made.

His processes. It hath in the vpper part two notable processes, long and as it were triangular, but the angles are obtuse or dull, and these processes together with the cauity in the midst, which is called *Sigmoides*, are in yong infants gristly, yet the anterior processe together with the cauity do quickly become bones, and the marke of the appendix is obliterated. The Posterior processe beginneth not to harden till after the seventh yeare, and then it is agglutinated or fastened to the rest of the bone.

The Elbow. The Anterior and vpper of these [figure 3, 5, 13, C] entreth into the Sinus or cauity of the Arme, [Figure 1, N] and is crufted ouer with a gristle on the inside; the posterior [D] is the thicker and the larger, which *Hippocrates* calleth *ἀγλῶνα*, *Galen* *ἀνέχρανον*, the Latines call it *Gibberum*, and we the *Elbow*; it entreth into the posterior cauity of the arme. [figure 2 O] The places of both these processes are rough, [Figure 13, CD] partly that the Ligaments might more strongly encompassse the ioynt, partly for the insertion of some muscles of the cubit, partly also to giue originall vnto the muscles that bend the Fingers; for which cause also the bone is rough at the roote of the processe: [Figure 5 and 13 L] the circumference also of the Sinus or cauity is rough [figure 13, IK] that from thence Ligaments might yssue, for in the middle of these processes there is a great Sinus [figure 3, 5 E betwixt CD] which receiue the gutture of the arme. This sinus is hollowed like a semi-circle, and being concluded or closed vp by these swelling processes, representeth the forme of the Greeke *Sigma*, and therefore by *Galen* is called *σγμοειδής*, and is crufted also ouer with a Gristle. But because it might be fitted exactly to the gutture of the arme, it hath in the midst an obrose protuberation, [figure 13 between FF] and at the sides on either hand is compressed, [figure 13, GG, HH] so that it may be compared to a cord compassing the gutter or rim of a wheele, that in it the cubit may be bent and extended: and from it is separated by a swelling line, least the Ell should slippe this way or that way: hence comes the mutuall ingresse of the bones one into another, which kinde of articulation is called *Ginglymos*, which we know not how better to expresse, then as the crookes of a paire of Hinges doe receiue and are receiued one of another. There is yet another Sinus at his outside smooth and crufted ouer with a gristle, [Figure 5. and 13, I] which receiue the head of the *Radius* or Wand. [Figure 7, II m]

From hence the Ell descending growes slenderer by degrees, [Figure 3, from A to B] and at the

the wrest is encreased with a small necke, [fig. 3, 4, 5, 6, 12 P] It hath also a round Appendix or an obtuse head inclining inward, [fig. 3, 4, 5, 6, 12 Q] about which the Wand is led vpward and downward. Finally it determineth into an acute proceffe, [R is the same figures] which is called *Styloides*, because it is like a probe or writing pen which the Ancients were wont to vse, not much vnlike a long Bodkin; and from this Bodkin there groweth a Ligament which firmeth or fasteneth the ioynt of the wrest with the Ell. At the basis also of this appendix there is grauen another vnequall sinus [f. 12 S] which distinguisheth the Appendix of the Ell from the wrest, and to it there is adioyned a gristle which is placed betwixt this articulation; [fig. 3, 4, 7, 8, 9, 10 T] another sinus somewhat long is grauen on the outside betwixt the two protuberations, [fig. 4, 6, 12 V] to guide and direct the tendon of the first muscle that extendeth the wrest. [T]

Furthermore, the Ell on the lower side vpon which it resteth when we leane, is gibbous a good way, [fig. 6, XYZ] and beside there are foure swelling lines which run throughout his length made for the vse of the muscles of the wrest. The first [f. 4 and 6] from z by a. [and f. 1, aa] The second ariseth or swelleth more toward the wrest [fig. 3, 5, 6*] for the originall of the Square muscle. The third is the sharpest and the roughest [fig. 3, 4, 5, cc] that from thence might arise a Ligament which like a membrane fasteneth together the Ell and the Wand. The fourth is prominent indeed but obtuse or blunt [f. 4, and 6, gg] from which three muscles haue their originall.

The forme of the Bone.

The vse of the Ell is, that the Hand without danger might be moued outward, and againe with facility returne inward.

His vse.

The other bone of the Cubit which is the vpper and the shorter, and occupieth almost the whole exterior part of the cubit [f. 7, and 8] is called *radius*, by some *Focile minus*, in Latine *Radius*, in English the Wand. This bone in respect of the Ell is oblique and is committed or ioyned thereto aboue and below, [f. 3, bi] so that aboue, the Ell receiueth the wand, below the wand receiueth the Ell; but in the midst they stand off one from another a good distance, [Figure 3, kk] partly that the Wand might more readily be moued vpward and downward, partly that a place might be made for the muscles which extend the Cubit.

The Radius or Wand.

This wand is articulated to the arme *per Diarthrosin*, by *Dearticulation*, hauing an oblique and slender necke; [f. 7, 8, 11, M] a round and depressed head, [f. 7, 8, 11, N] crufted ouer with a gristle for more agility of motion, but where it regardeth the arme it hath a round or superfiary bosome [f. 11 O] into which the head of the arme entreth, [fig. 1, P] and at this head the Wand when the Ell is at rest is turned downward and vpward. A little aboue the necke it hath a rugged and abrupt proceffe or protuberation [f. 4, 5, 7, 8, 11 q] into which is inserted the tendon of the anterior muscle that bendeth the Cubit; so also through his length there runneth an acute and bunching line [fig. 3, 4, 7, 8, rr] vnto which is fastned a Ligament that ioyneth the Ell and the wand together on either side, with which line the bone is compressed [fig. 3, 7, f. and fig. 4, 8, st] to giue way to the Muscles. The bone also it selfe throughout the midst of his length is rough, [Figure 4, 7, 8, u] so made for the insertion of two muscles of the wand. This wand below at the wrest is dilated, and groweth thicker, because of a bosome therein to be made for the articulation of the wrest with the cubit.

It also hath an appendix [f. 3, 7, n] with a double bosome crufted ouer with a gristle, [f. 5, 12, o] that therein the head [f. 4, 12 p] of the appendix of the Ell which is also couered with a Gristle might be moued. This bosome or cavity was made double [fig. 3, 10, xy] because there are two bones of the wrest articulated therewith, to wit, the first and the second: [14. 22 f. 1, 2, 4, 5, char. 1, 2] also where these two are ioyned together, the sinus protuberateth moderately in the midst, [f. 3, 10, z] yet beside that protuberation it hath also a proceffe. [f. 3, 7, 9, 10, a]

His Appendix dancet.

The outside of the Appendix of the wand, as also of the wrest is gibbous, and therein hath foure sinus insculped or grauen, [fig. 4, 7, d, e, z, n] thorough which the tendons of the muscles might be more certainly conducted through the annular Ligament. The fourth of these [n] is very shallow but rough, for it bringeth forth a transuerse Ligament and beside swelleth vpward, for into that swelling the tendon of the Long muscle which turneth the wand vpward is infixed.

The Sinus

There is also in the same place another sinus common to the Ell and the wand [fig. 4, o] made for the Tendon of the muscle that extendeth the little Finger.

Both

The confi-
stence of the
Bones of the
Cubit.

Both these bones of the Cubit are of a solid and hard substance excepting their Appendances, and full of final holes bored also to containe marrow, but if you consider them apart they are one contrary to another in respect of their parts, for the vpper part of the Ell is the thicker the lower is the thinner, contrariwise the vpper part of the Wand is the thinner and the lower is the thicker. Finally, the vse of the wand is to moue the Hand downward and vpperward, as also in compasse, although the Ell, saith *Archangelus*, be not moued.

CHAP. XXX

Of the Bones of the Hand properly so called, that is, of the Wrest and After-wrest.

THE Bones of the Hand doe follow in the next place which are of foure sorts: first those of the wrest; secondly those of the afterwrest; thirdly the bones of the Fingers; fourthly the Seede-bones called *Sesamina*.

The wrest.

The Wrest is called in Greeke *καρπός*, in Latine properly by *Celsus brachiale*, but the Greeke word is also among the Latines grown into vse, which is *carpus*: we call it the Wrest, which is that patt of the Hand which is articulated to the Cubit and to the After-wrest, and is construed or made of eight bones; most Anatomistes say of seuen, but because the first is thought to be double, therefore saith *Archangelus* we account eight.

Eight bones.

These bones are distinguished in a double order, the reason was that the Hand might be moued with more agility. [ta. 22, fig. 3, char. 5, 6] These eight bones do differ in their magnitude, forme, situation and consistence, and in the first generation are all gristles and not bones but in proceffe of time they become hard and grow bony. Their substance is spongy as are all the rest of the bones which of gristles become bony, of which kinde are all *Appendices*, the bones of the wrest and such like. These bones are not without marrow, and beside are couered ouer with gristly and strong Ligaments, whereby they are so compacted together (but the vpper more then the lower) that if you doe not deuide the Ligaments and the Membranes also, you will thinke that they are but one bone, which hath deceived some Anatomists.

Their surface.

They haue a double *superficies*, the one *exterior* and gibbous [Fi. 4] the other *interior* and sinuated or concaveous, [fi. 3] and above, where they are ioyned to the Cubit, as also below where they are articulated with the After-wrest they are all smooth and crufted ouer with a gristle: but beside that gristle where they touch one another they haue also *sinus* or cauities

Their articulation.

and heads crufted with a slippery gristle: and this articulation of these bones is to be referred to that third kinde which *Galen* calleth *Neutrall* and doubtfull; for in respect of their composition it may be called *Dearticulation*; and in respect of their pure motion it may be called *Coarticulation*. Foure of these are reposed in the vpper ranke of the wrest which is next vnto the Cubit, [ta. 22, Fi. 1, 2, 3, 4, ch. 1, 2, 3, 4] the other foure in the lower ranke. [cha. 5, 6, 7, 8] But because these bones want proper names, therefore they are distinguished onely by their order and number.

The first bone of the wrest.

We call that the first which maketh the inside of the vpper ranke. It is a long bone curved inward and articulated to the Wand together with the second bone of the later ranke, and his head entereth into a *sinus* of the second bone on the inside. Another head it hath also which is greater then the former and lower, and entreth before, into a *sinus* formed by the fift and sixt bones. It hath also a notable *sinus*, wherein together with the second bone it admitteth on the inside the head of the seuenth bone.

The second.

The second bone of the wrest leaneth vnto the former and is lesse then it: it is reposed behind in a *sinus* insculped in the appendix of the Wand, [ta. 21, fig. 3, 10. xy] and is ioyned on the fore side with the first bone, below with the seuenth, behind with the third hauing a plaine *superficies*.

The third.

The third is ioyned with a plaine *superficies* also to the Ell and his gristle: [ta. 21, fi. 3, 4, 7, 8 T] againe to the second and the fourth; and below it hath a large head, which entreth into a *sinus* of the eight bone.

The fourth.

The fourth bone is called *Os rectum* the Right-bone, and is the hardest and the least of all the rest, and almost round, for it is neither hollow nor protuberated as the rest are. It is ioyned with a depressed head to the externall side of the third bone, and seemeth also to be a little inserted into the proceffe of the eight bone; otherwise it toucheth no bone of that ranke, but in the vpper part thereof the Tendon of the muscle that bendeth the wrest is inserted; below, two muscles haue their originall which goe into the little Finger.

TABVLA XXII.

B 7, The first bone of the Fore finger. **C 7**, the round head of the bone of the afterwrist. **D 7**, a Sinus of the Fore finger receiving the foresaid head. **E F 8**, the first bone of the Fore finger **E**, the second **F**. **G H 8**, two small heads of the first bone of the Fore finger. **I K 8**, two Sinus of the second bone of the Fore finger. **L 8**, a Sinus betwixt the two small heads of the first bone. **M 8**, a small head betwixt the two Sinus of the second bone. **N 9**, the second bone of the Fore finger and his two heads. **O 9**, the third bone of the Forefinger containing a Sinus. **Fig. 10.** **A 10**, The inside of the naylor hollow. **B 10**, his soft roote which the skin is wont to cover. **C 10**, the outside of the naylor gibbous. **Fig. 11.** **A 11**, the lower side of the Seede-bone that is placed before the first ioynt of the thumbe. **B 11**, the vpper part of the same which is next vnto the ioynt. **C 11**, the vpper of another Seede-bone. **D 11**, the lower part. **aa 11**, the Seede-bones at the ioynt of the thumbe. **bb 11**, the Seede-bones at the ioynt of the Forefinger. **cc 11**, Seede-bones placed at the little finger.

A 1, 2, The first bone of the Afterwrist supporting the thumbe.

I, II, III, IIII, The four other bones of the Afterwrist ioyned to the fingers.

B C 1, 2, the two bones of the thumbe.

DEF 1, 2, the three bones of the fore-finger, the same also in the rest of the Fingers.

G 3, 6, The gutter of the fist bone of the wrist whereto the first bone of the Afterwrist is articulated.

a b 6, the length of this gutter:

c d 6, The inside of the gutter **c**, the outside **d**.

e 3, 4, 6, A Sinus at the gutter **c**, which the second bone of the afterwrist doth touch.

H 3, 4, 6, The Sinus of the fist bone of the wrist whereto the second bone of the afterwrist is ioyned.

f 3, 4, 6, a part of this Sinus which the third bone of the afterwrist scarcetoucheth.

I 3, 4, 6, the Sinus of the seventh bone of the wrist, to which the third bone of the afterwrist is ioyned.

K 3, 4, 6, The place of the eight bone of the wrist which admitteth the fourth bone of the afterwrist.

L 3, 4, 6, a Sinus of the same bone receiuing the fist bone of the afterwrist.

M 1, 2, a small bone placed sometimes outwardly at the ioynt of the eight bone of the wrist.

N 1, 3, 6, a proceffe of the same eight bone swelling out into the ball of the hand.

O 1, 3, 6, the proceffe of the fist bone of the wrist from whence groweth a Ligament.

P 2, an appendix of the wrist whereby they are ioyned to the afterwrist.

Q 2, Another appendix which with the head entreteth into the Sinus of the fingers.

R 1, 2, the distance betwixt the bones of the afterwrist.

S 1, 2, two Seede-bones set at the inside and outside of the first ioynt.

T 1, 2, two Seede-bones in the first ioynts of the four fingers.

V V 1, one Seede-bone in the second and third ioynts of the fingers.

Char. 1, 2, 3, 4, 5, 6, 7, 8, these numbers in six fingers doe shew the eight bones of the wrist.

Fig 7, 8, 9.

A 7, the bone of the afterwrist which supporteth the fore fingers.

The fifth

The fifth bone of the wrist on the outside toward the thumbe, receiveth into the vpper sinus the posterior head of the first bone on the inside, it receiveth into another Sinus the head of the sixth Bone. It hath also a lower Sinus [tab. 22. fig. 3, 6 G] which is long [fig. 6 a b] grauen somewhat deepe in the inside and the outside, [fig. 6 c d] wherein it receiveth the head of the first bone of the thumbe, as also a part of the fifth bone of the After-wrest. [fig. 3, 4, 6 e] It produceth also on his inside a proceffe [fig. 1, 3, 6 O] to make way for the Tendons of the Muscles that bend the fingers, and so with the fourth bone maketh that passage hollow.

The sixth

The sixth Bone receiveth into his sinus on the backside the first bone, and his onward head entreteth into the sinus of the fifth, his inner head also is ioyned with a plaine superficies to the seauenth bone. This bone also receiveth the first bone of the After-wrest which supporteth the roote of the fore-finger, [fig. 3, 4, 6, H] but the second more obscurely, [fig. 3, 5, 6, f.]

The seauenth

The seauenth, which is the greatest of the second ranke (as the sixth is the least) is easily luxed because of his lax connexion. It hath a round head which entreteth into the sinus which is common to the first and second bone. It is also loosely articulated on the inside to the sixth bone, on the outside with a depressed head to the eighth bone, whereto it is likewise ioyned by interposition of a gristly Ligament. Finally, it is fastned to the second bone of the After-wrest.

The eighth.

The eighth bone which like a wedge is placed between the third and the seauenth bones is ioyned at the left side with a depressed head to the third bone. On the right side with a depressed Sinus to the seauenth: before, his superficies is broad, [fig. 3, 4, 6, K] whereby it is ioyned to the third bone of the After-wrest and receiveth in a certaine Sinus [Fig. 3, 4, 6 L] the Head of the fourth bone of the After-wrest. It also produceth in the inside of the wrest a proceffe which inclineth from the out side inward, exculped or grauen like the letter C. to make the hand hollow to containe the tendons of the muscles that bend the fingers. Out of the toppe of this proceffe groweth the transuerse Ligament of the wrest, and to it is fastned a seed-bone- [Fig. 1 and 2 M] And thus much of the wrest.

The after-wrest.

The next part of the Hand is called in Greeke *μετακαρπιον*, in Latine *Postbrachiale*, by some *Ima palma*, wee will call it the After-wrest. It is that part of the hand which is betwixt the wrest and the rootes of the Fingers, and consisteth of foure bones, of five say some Anatomists, who reckon the first bone of the thumb with the After-wrest, because we do not meete with it so bare as the bones of the rest of the Fingers are, but it lyes deeper as the other bones of the After-wrest. [tab. 21, fig. 1 and 2]

The bones of the after-wrest

These bones of the After-wrest being placed betwixt the wrest and the bones of the Fingers, [char. I. II. III. IV] are ioyned to the wrest by *Coarticulation*; or rather by *doubtfull articulation* as they are ioyned to the bones of the Fingers by *dearticulation*; for all the bones of the After-wrest where they regard the Fingers do end into a rounde head, that so they might enter into the shallow or superficiali cauities of the subsequent ioynts. Among themselues they are ioyned onely by contaction of their extremities towards the bones of the wrest, where they are fastned with gristly Ligaments. [fig. 2 P]

These bones of the After-wrest are longer then the bones of the fingers, and the first of them which standeth before the fore-finger is the longest and thickest of them; all the rest are by degrees shorter and thinner; beside they are all somewhat broader on the outside then they are on the inside.

Toward their extremities they grow thicke and haue *Appendices* growing to them aboue and below, [fig. 2 P Q] out of which *Appendices* yssue Ligaments whereby these bones are ioyned together though that coniunction be somewhat dissolute or loose: for the vpper are fastned to the bones of the wrest, but the *Appendices* themselues are tyed together by the interposition of a gristly Ligament. The lower *Appendices* which are the greater, are fastned to the bones by coalition, for their head is round and long, forward and backward, lengthned out somewhat to the sides, and crufted ouer with a gristle, and these heads do insinuate themselues into the Sinus of the first bones of the fingers.

These bones are after a sort round, yet haue they as it were three sides, two inward sides ending into a line the better to giue way to the muscles called *Interossei* or the *bone-bound* Muscles, [fig. 1] and one externall which maketh the hand plaine. [fig. 2]

The distance betwixt them

There is also betwixt these Bones an intermediate distance, [fig. 1, 2, R] in which distance the *bone-bound* muscles are placed; that is to say, two in euery distance. And because the

the palme of the Hand should not swell too great by the bellies of these muscles and so bee made lesse fit for comprehension, as also that the place might be sufficient to containe them; these bones on the inside which is next vnto the palme are curued and their outside is gibbous: they are also cornered and haue swelling lines in them made for the insertion of the muscles in that place.

The first bone also where it is articulated with the wrest hath a processe [*tab. 22. fig. 1,* *aboue char. 6, and 7.*] whereinto the second muscle that bendeth the wrest is inserted. In like manner the fourth bone swelleth on the outside [*fig. 1, aboue M*] into which swelling the third muscle of the wrest is inserted. Note also that the palme of the hand is especially made hollow by the first bone of the thumb (which some make the first of the Afterwrest) and by the fourth of the Afterwrest, for the other three doe helpe that cauity but little.

Finally, the bones of the Afterwrest are fistulated or hollow to containe the marrow. Their vse is to establish and strengthen the Palme, that it might comprehend or containe whatsoeuer it is applyed vnto with more stedfastnes. And thus much of the Wrest and Afterwrest.

CHAP. XXXI.
Of the Bones of the Fingers.

THE Fingers which make the third part of the Hand are construed or compounded of fifteen bones: for we say (saith *Baughine*) that the thumbe also hath three bones. And because they stand as it were in rank, therefore the Grecians haue called their order *κατάγγρας*, as it were the Files of a battell disposed in order.

The particular bones doe want proper names, and therefore are expressed by the names of the fingers to which they appertaine, as the first bone of the thumbe or the forefinger; the second and the third and so in the rest. Their number was with wonderfull wisdome ordayned as was fittest for the facility and variety of motion, for if they had beene more they could not haue beene perfectly and strongly extended: againe, if they had beene fewer the fingers could not haue beene moued into so many formes. *Galen* in his first and second bookes *de usu partium*, hath so elegantly discoursed of the counsell and wisdome of Nature in this poynt that it will not onely delight any man that shall reade it, but also transport him (as himselfe seemeth to haue beene transported) into an admiration of the wonderfull wisdome of the Creator.

The forme of these bones on the outside (excepting the last) is gibbous and crooked, on the inside it is plaine and somewhat hollowed or sadled, partly because wee apprehend with the inside of the hand, partly because more tendons run into the inside then into the outside. Furthermore on their inside there are certaine lines running on both sides the bones throughout their length, from which lines certaine Ligaments are produced; which like rings doe encompassse the Tendons and hold them stedfastly in their places. These bones although they be hard and fast or dense that the hand might vse them in manifold employments without danger or annoyance, yet they haue a cauity or hollownesse within them which containeth marrow.

Their magnitude is diuers, for the first bone of each finger is larger in all the dimensions, that is, thicker, longer and broader then the second, [*tab. 22, fig. 1, and 2,*] in like manner the second is greater then the third, for Nature provided that the thicker finger should haue the thicker bones, and the longer finger the longer bones. Notwithstanding albeit their magnitude is not the same, yet they appeare all equall, & all the fingers are brought together into one right line when wee would comprehend any round body. Moreover they are in the beginning broader, and so grow narrower by degrees. At the ioynts all the bones are somewhat thicke, that the *basis* being the larger, the construction might bee more substantiall: in their length they are not all of a thicknesse least their quantity or waigh should haue beene offensive. The swelling protuberations of the bones are called *κόρυλοι* *Knots*, but in English Knuckles.

The bones of the first and second ioynt haue *Appendices* aboue and below made for the originall and insertion of muscles: the bones of the third ioynt haue *Appendices* onely aboue; for the very end or head of the fingers being not articulated againe but onely ioynted with flesh or a nayle, needed no Appendix at all: they are also cruisted ouer with gristles that the ioynt might be at all times glib and easie to moue.

The first bone
of the thumbe.

The first bone of the thumb [Tab. 22. fig. 1 & 2 A] aboue hath a long sinus, but before & behinde it buncheth out, that it might ioyne with the farrow or gutter of the fift bone of the wrest. It is manifestly mooued directly outward and inward toward the palme; side-ward toward the forefinger, from which also it is remoued by reason of the length of the guttur, and beside it is turned circularly. But if the head of the bone of the wrest bee produced more backward, then is the bone of the thumbe easily and directly bent backward, so haue I seene a man able to lay the Naile of his thumbe vpon his wrest. Some also will in like manner turne all their fingers vpon the backe of their hands. Aboue, this first bone of the thumbe hath a head but not perfectly round, which entreth into the sinus of the second bone.

The second

The second bone of the Thumbe where it regardeth the third is diuided by the Mediation of a long sinus [fig. 8. L] into two long heads; [fig. 8. G H] protuberating before on either side.

The third.

The third bone hath two Sinus [fig. 8. I K] distinguished by a long knot, [M] whereinto the heads of the second bone are receiued: againe the knub of the third bone entreth into the Sinus of the second; so the second is receiued of the third, and receyueth the third, making thereby a *Ginglymos*, wherein the two Bones are so straightned, that onely the third bone can be bended or extended.

The Bones of
the Fingers.

After the same manner are the articulations made of the rest of the fingers, for they haue two heads and two bosomes. But the first ioynts of the foure fingers haue but one head and one bosome, because the bones of the After-wrest haue each but one Head, which looketh especially into the inside of the Hand, and hath more a boundance of gristly substance about it. The Sinus in the first bone of the foure fingers is orbicular, and aboue that head the first bone is bent, extended and moued to the sides. The third bone also it selfe swelleth into a gristly top and rough head [fig. 9 O] whereinto is inserted the Tendon that benderh it. Moreouer, all the inside is rough and vnequall, and at the end it is not knotted as the first and second bones are, but lyeth plaine to giue way vnto the Nayles.

CHAP. XXXIII. Of the Seede-bones.

How to finde
the seed bones

THE last thing to bee considered in the Hande are the Seede-bones, called *moeddy* [tab. 22. fig. 9.] because they are like *Sesamum* seede. These Bones are placed in the ioyntes or knuckles of the fingers and of the toes: for the most part they grow vnto the Tendons and lurke vnder them; and therefore he that would make demonstration of them must seeke for them in the dissection of the Tendons of the Muscles which are seated about these bones. Moreouer, they are so entangled with ligaments, that if you desire to clense the bones, you shall take them away with the Ligaments vnlesse your care be the greater. They are crufted ouer with gristles and touch the slippery side of the other bone. Solid they are, round, a little depressed, sometimes gristly, sometimes bony, within fungous and full of pores, wherein they containe a iuyce which serueth them instead of marrow.

Their number

These Seede-bones are commonly in each hand twelue; one standeth before the middest of the third ioynt, two at the second ioynt of the thumbe, [fig. 1 and 2. S] two lesser which are gristly in the first knuckles of the foure fingers [fig. 1 T] which leane vpon the tendons, and are bent on either hand at the sides of the ioynt with the double tendon. In the rest of the ioynts of the foure fingers, that is, in the second and the third at each ioynt there is one bone, which is placed before the middest of one single tendon, and these are much lesser, [Fig. 1 V] and as it were gristly, but yet larger in the hands then in the feete: in old men they grow big and almost plaine, in children they are but gristly and scarce conspicuous in the Tendons. Their number is not certaine as is the number of other bones, partly because they are so small that they are lost in dissections, partly, saith *Archangelus*, because for want of seede Nature omitteth somethings which are lesse necessary in the frame of the body.

There is one little bone amongst these Seede-bones which may be numbred twice [fig. 12 M] because it is found in the hand neere the connection of the bone of the after-wrest which sustaineth the little Finger with the eight bone of the wrest, for it filleth vp a place there on each side.

The vse of these Seed-bones is foure-fold: the first, that in certaine motions by their hard-

hardnesse they might be better able to receiue and sustaine the violence of the bone mo-
ued; for the Tendon is defended with such a small seed-bone to keepe it from shouldring
vpon it selfe; for, in the extention of the fingers they insinuate themselues somewhat into
the space of the ioynt, and returne or holde the Tendon, least in the motion it should fall
from the ioynt as it swels.

The second vse is to hinder the bone, at which it is set, from luxing easily out of his ioynt,
and so they are a defence to the ioynts, like as in the great ioynt of the knee the whirlbone
is as it were a shield or muniment to keepe the bones from luxation.

Their third vse is to fill vp the distances which remained empty betwixt the bones of the
fingers, and so againe they adde strength vnto the ioynt.

Fourthly, to make the action of the hand which is apprehension more firme and con-
stant. And this shall bee sufficient to haue said concerning the bones of the whole hand.
Onely we will adde.

That on the outside of the fingers there are nayles set [Tab. 22, fig. 12] to make their
apprehensions more distinct and strong, and these nayles are neyther longer nor shorter
then the ends of the fingers are, and therefore when they grow longer wee pare them off,
otherwise they would hinder apprehension. And thus much of the bones of the hand.
Now wee proceed vnto the Foote.

CHAP. XXXIII.
Of the bones of the Thigh.

HE Ancients called all that the foot which is betwixt the top of the Thigh and
the top of the great toe. The bones of the Foote are 42, and belong some of
them to the Thigh, some of them to the Legge, and some to the Foote com-
monly so called.

The Thigh is called by the Grecians *μυῖς*, by the Latines *Femur a ferendo*, because the
creature is borne or sustained especially by these parts. It is also called *Femen* although
saith *Varro* in his fourth booke, *Femina* are properly the inner parts of the *Coxa*, and *Femo-
ra* the outward. The bone of the thigh is but one as is the bone of the arme. [Tab: 23, fig.
1, 2, 3.] In a man and an Ape it is the longest bone of the body, in other creatures where-
in a great part of it lyeth hid, it is shorter then the Legge as it is in Birdes. The position of
it is obliquely inward to the knee from the Hip-bone. The figure of it is long, round and
strait, but not exquisitely because it descendeth obliquely inward at the knee to make the
station or standing, the walking and running more firme and strong, which also *Galen* eu-
idently declareth in the 9 chap. of his booke *de vsu partium*; for those men whose Thighes
are more streight and direct then it behooued, are called *Vari* and become lame in their
knees. And it behooueth much that wee should marke this posture of the Thigh bone
(being thereto counselled also by *Hippocrates*) least if it be broken and be to be restored a-
gain, he that mends the breach should turne it the wrong way.

On the foreside it is gibbous, and that is profitable not onely for Session and sitting;
but for many other labours or operations which are performed when wee sit, as if a man
would write vpon his knee, hold a Viall or any other thing betwixt his legs, or lay one leg
ouer another. In the sides it is round and smooth on both hands, on the backside doked
or hollow: aboue it endeth into a head, a necke and two processe, below it determines
into a head which hath two productions and bosomes.

The vpper head [Tab. 23, fig. 1, 2, A fig. 3, XT the vpper] is wholly made of an orbicular
Appendix which it hath, and is thicke and the largest head in the whole body. In so much as
Hippocrates, in his booke *de fracturis*, calls it by an excellency *ἀρθρον*, *Articulū* the ioynt. This
head is round and long, the better to enter into the cup of the hip-bone which is not onely
deepe of it selfe but indeed deeper by a large gristle that compasseth the verges thereof.

And the reason why this cup was so deepe and the head so long, was that the articu-
lation should bee exceeding strong because of the enorme and huge waight which the
thigh was to sustaine. It is therefore articulated by *Inarticulation* which is a kinde of
Dearticulation, and beside to strengthen it the more, and to fasten the two bones together,
there ariseth out of the cup of the hip an exceeding strong and round ligament which is
implanted into his *Sinus*, [Tab. 23, fig. 2, B] seated vnder the top of the head which is nar-
row and deepe. The head also is smooth and crufted ouer with a gristle, that so the thigh

Femina;
Femora.

The figure of
it.

Head;
The vpper

might more easily and with greater expedition be bent, extended, mooued to the sides and circumflected or turned about.

The necke.

Vnder the head is the necke of the thigh called *αυχὴν Cernix*. [tab. 23. Fig. 1, 2, 3, D] It is long and reaching vpward, reclined also obliquely inward, least the thighes motion should haue beene hindered. Out of the necke where the bone groweth broader [vnder D] doe arise two knots which they call processes, or *Trochanters*, or *Rotatores*: and these *Trochanters* haue *Appendices* [Tab. 23. fig. 3. the middle x] which in children new borne (as also the head it selfe) may easily be separated, but in growne bodies they are so vnited with the prominent parts [fig. 2. Q with v. fig. 1, 4 with b] that there remaineth scarce any signe or footstep of an Appendix.

The vpper of these [Fig. 2, Q v] is the greater, and of all the processes in the body which are not ioyned to another bone simply the greatest: it bendeth vpward and outward. The lower [Fig. 1, 2, 4] is farre lesser and looketh backward and inward. And both these are called *Rotatores*, eyther because they were made to turne the Thigh, or rather because the muscles which accomplish the motions of the Thigh are inserted into them. The first is called the great Trochanter and *γλουτοῦ*, eyther because it is something like the Buttocke, or because the muscles of the buttocke are inserted into it. The other is called the lesser Trochanter. These two processes are ioyned together by a line which buncheth out behind and runneth from without inward and so the bone of the Thigh becommeth round.

The vse of the Trochanters.

The vse of these Trochanters is like a little hill to admit the insertion of some muscles and to others to afford place of originall, for into the inner Trochanter is infixed the tendon of the first and second muscles which bend the thigh: close vnto this there runneth a rough line [Fig. 2, c c] obliquely downeward and backward which seemeth to bee parted into two and to reach vnto both the heads, but is more evidently terminated at the vtter head, and into this line is the eight muscle of the Thigh implanted adhering verie closely thereto, for by the helpe of that muscle especially we stand vpright.

The sinus of the thigh.

At the vtter proceffe there is a *Sinus*, certaine impressions, and a line to bee obserued. This Sinus [Fig. 2, x] regardeth the head of the Thigh, and into it are the ninth and tenth muscles of the thigh inserted. The impressions are foure at the vtter gibbous part which receiue the Tendons of foure muscles. The first in the backward and lower side; [Fig. 2. Q] it is a large impression which receiue the tendon of the first muscle of the thigh; [fig. 1, τ] in the fore side which is also the rougher and receiue the tendon of the second muscle; the third in the vpper and vtter part [Fig. 1, β below τ and υ] which is gibbous and made to receiue the tendon of the third muscle: the fourth [Fig. 1, and 2, υ] is in the very tob of the proceffe and narrower then the rest, and admitteth the tendon of the fourth muscle. But from the roote of this proceffe on the anterior and the exterior side ariseth the scauenth muscle of the head. The line wee spake of is rough and runneth from the first impression downward and somewhat obliquely through the backside of the thigh, and into it is the first muscle of the thigh implanted.

The line.

Now below the middle Region the Thigh as it descendeth [Fig. 2, from d to e] it becommeth thicker, is dilated and depressed, [Fig. 2, e] in which depression a veine, an artery and a nerue do securely run, and at length it determineth into an ample and broad head; which latitude is made by a large Appendix. [tab. 23. fig. 3. x y the lower] Out of the backside of this head are produced two processes as it were two other heads, [Fig. 1, and 2, E F] betwixt which there is a large space left about an inch broad, [Fig. 2, I] which receiue a protuberation swelling out of the head of the Leg-bone.

The lower heads of the thigh.

These two heads are on the outside rough, but their superficies is smooth, because of a gristle which compasseth them to make the motion at the knee more expedite or easie. These heads doe bend more backward, and in the sides are scarce depressed at all, because of the articulation of the Thigh with the Legge-bone. [ioyne tab. 23. fig. 1, and 2. E F I with tab. 24. fig. 7, G F] which is made by *Ginglymos*, for these two heads of the Thigh doe fit in two bosomes or cauities of the Legge-bone, and the protuberation of the Legge-bone which swelleth vp betwixt his sinus [tab. 24. fig. 7. I betwixt G and F] is receiued by the posterior sinus of the Thigh-bone. [tab. 23. fig. 2, I] Moreouer the Thigh is fastned with the Legge below (as it was aboue with the Hip-bone) by a strong ligament produced from the protuberation of the Leg-bone.

Of these heads, one is internall which is the thicker; another externall which is broader and more depressed, least both of them should bee equally articulated to the Legge and

Table 23. Figure 1 and 2 sheweth the fore and hinder part of the thigh-bone.

Figure 3 sheweth the thigh, whose Appendices wee have remooved out of their place, and disioyned with a little distance.

Figure 4 and 5. The fourth sheweth the anterior and rough side of the Pattell bone; the fift his posterior part crufted over,

TABVLA XXIII.

2, The largeness of the thigh in this part. *f* 1, a roughness from which the eight muscle yssueth. *g*, *h* 5, a knob of the Whirle-bone going into the sinus marked with *l*, which is betwixt the heads of the thigh. *i* 5, a sinus fitted for the inner head of the thigh. *k* 5, a sinus agreeing with the externall head of the thigh. *l* 5, The lower a sperity or roughness. *m* 4, The foreside of the pattell or whirle-bone rough or vnequall.

and so the oblique motion made by the muscle of the Ham called *Popliteus* bee interrupted; for this muscle yssueth from the externall head where it is exasperated with small cavities, and these heads (as he saide) doe enter into the sinus of the Legge-bone. From these processes as it were, the three first muscles that mooue the foote take their Originall, as also the tendon of the fift muscle of the thigh is infixed into the side of the inner head, [*M*] where the compressio is marked. [*fig. 2, R*] Their sides are full of blind holes, out of which doe yssue the Ligaments which hold together the ioynts of the knee.

They haue also foure sinus or cauities, two in the middle of the head, and one in the sides on either hand. The first of these which is the forward [*tab. 23. fig. 1, H*] is crufted over with a gristle and receyueth the protuberation of the Pan: [*Fig. 5, g b*] the second and the backward. [*Fig. 2, l*] is deepe, rough and vnequall, and receyueth the protuberation of the Leggs

A 1, 2, The head of the thigh going into the Cup of the Hip-bone.

B 2, A sinus in the head of the Thigh, into which is inserted a round Ligament.

C 1, 2, The coniunction of the Appendix of the thigh with the bone it selfe.

D 1, 2, 3, the necke of the thigh.

E, F, the two lower heads of the thigh.

G 1, 2, The coniunction of the lower appendix.

H 1, 2, A sinus betwixt the two heads of the Thigh.

K 2, A part of the lower head of the thigh from whence the first muscle of the foote doth proceede.

L 2, Another part from whence the second and third Muscles arise.

M 2, Another part to which the Tendon of the fift Muscle of the thigh is infixed.

N 1, 2, A sinus of the outward side of the head for the fourth muscle of the legge.

O 2, A sinus of the inside through which the tendons doe passe.

P 2, A protuberation at which the sayd tendons are reflected.

Q 2, the vtter processe of the thigh, and betwixt *Q* and *D* is the sinus.

R 1, 2, the vnion of the processe with the thigh.

S S 2, a rough line from the impression of the externall processes.

T 1, the anterior impression of the internall processes.

U, betwixt *T* and *V* another impressio higher then the former.

V 1, 2, the fourth impressio in the toppe of the processe.

X 3, Foure *X*, shew the foure appendices of the thigh.

Y 3, Three *Y* shew the three heads of the thigh.

Z Z 3, Two processes of the thigh.

a 1, the interior processe of the thigh.

b 1, the coniunction of the processe with the thigh.

c c 2, a line descending obliquely from the inner processe.

d d 2, a line running thorough the length of the thigh.

leg-bone: [tab. 24, fig. 7, I] the third is at the outside of the head, [fig. 12, N] through which the tendon of the fourth muscle of the Legge (reflected in this place) is safely transported: the fourth Sinus is at the inner head [fig. 2, O] wherein the tendons of the first, second, third and fift muscles of the legge are safely conuayed.

On the forefide at the roote of the necke the thighbone is large and rough, [fig. 1, f] so framed for the originall of the eight muscle of the Legge: on the backside it buncheth out with a rough and vnequall line [fig. 2, dd] into which the fift muscle of the thigh is infixed.

The vse of the thigh.

Finally, on the outside throughout the length of the bone there is a large sinus or cavity made not so much for lightnes as to containe greate store of marrow for nourishment, and therefore the vpper part of the bone, but especially the lower, is thrilled through with many small perforations whereinto the veynes are admitted which bring blood vnto that place. The vse of the thigh is for progression; now some creatures doe moue right vp, some bending downeward, and this variety is made by the different insertion of that round and strong ligament which yssueth out of the Thigh and is inserted into the cup; for if the insertion bee made, saith *Archangelus*, toward the vpper part of the cup, then the creature walketh streight vp as a man doth; if it bee inserted toward the laterall part, then his gate is prone or inclined to the earth, as an Oxe or an Horse. And thus much of the bones of the Thigh.

CHAP. XXXIII.

Of the two bones of the Legge.

The names of the bones of the legge.

 We call all that the Legge which is betwixt the knee and the instep, and it hath two bones as the Cubit had, [tab. 24, fig. 1, and 2] and surely if it had consisted of one thicke and great bone it would not haue beene so fit for motion, which would haue beene hindered by the gravity or weight thereof, as *Galen* excellently sheweth in the 13 chap. of his third Booke *De vsu Partium*. Of these bones the inner is called *ἡνίκον*, *Tibia*, carying the name of the whole, and so we call it the Leg-bone, [fig. 3, 4] the vtter is called *ἡνίκον* *Fibula*, [fig. 1, and 6] we call it the Brace bone or if you will the Shinne bone.

The Leg-bone is called *Tibia*, haply because it is like a Fluite, it is called also *Canna maior*, for so also a Fluite in latine is called. If you will (for difference sake) we may call *Tibia* the Shanke, and *Fibula* the Shin-bone, or if you had rather retaine the latine names call *Tibia* the Leg-bone and *Fibula* the Brace bone. The Leg-bone is the inner and the thicker, somewhat shorter then the Thigh to which it is ioyned, otherwise it is the longest of all the bones.

His sinure.

The figure of it is long and three square, thicke aboue and below and eeked with an Appendix. [tab. 24, fig. 1, and 3, ABDD] It is also made vnequall with long cauities and lines, and is articulated aboue with the Thigh, below with the *talus* or Coccoal, or bone of the instep by *Ginglymos*.

His vpper part

The vpper part which they call the vpper head is broader then the lower, for the Legge was made to beare the Thigh, and this bredth is formed by an Appendix which is set like a cup vpon the head of the bone. [tab. 24, fig. 1, 3, AB] This Appendix is thicke and before inclineth something more downward then it doth behind; [fig. 1, 3, B] it hath two long Sinus, [fig. 2, and 7, FG] which are but shallow and crufted ouer with a slippery Gristle where into it receiue the two heads of the thigh, [ta. 23, fig. 2, EF] and so a *Ginglymos* is made. But because the proper cavity of these Sinus was not deepe enough to receiue the length of the heads of the thigh, an amends is made and the Sinus increased in all creatures by a peculiar gristle [fig. 8] like a halfe moone, which is therefore called *Cartilago Lunata*, the *Crescent Gristle*; and this gristle is fastned by ligaments. This gristle is moouable and thicke in the circumference or Verge, [fig. 8, N] and yet toward the Center it is alwayes attenuated, [fig. 8, OO] toward the Center I say, for it doth not reach so farre as to the Center but endeth on eyther hand into sharpe tops, [fig. 8, PP] yet so, that before these tops doe meete (for the right is ioyned to the left) but behind they are more distant to giue way to a thicke ligament that passeth betwixt them. The gristle also is slippery, smooth, and soft, full of an vnctuous or oily humor to further the motion of the ioynt, and it supplyeth the office of a ligament.

His gristle.

These two Sinus are separated by a rough and vnequall protuberation [fig. 7, HIK] growing out of the middle superficies of the leg and shank-bone, which protuberation is receiued by the Sinus of the thigh [tab. 23, fig. 2, I] which is betwixt his two heads. Out of the

the rough and sinuated top [tab. 24. fig. 2, 3, 4, 7 I] of this protuberation on the backside yssueth [tab. 24. fig. 2 4 7 K] a strong Ligament which is infixed into the middle of the sinus of the thigh, [tab. 23. fig. 2 I] that the ioynt being thus on euery side defended, might the better be contained in his owne place. From the anterior part of the protuberation [tab. 24. fig. 7 H] which is rough and sinewated, are produced certaine Ligaments which on the foreside of the protuberation doe ioyne the gristles together which encrease the cauities of the shanke, [fig. 8 LM] although also they grow together by the interposition of that orbicular or round Ligament which compasseth the knee.

Out of the Appendix at the vtter side of the legge ariseth a little head [tab. 24. fig. 4 R] ^{His Head.} which is crufted ouer with a gristle and entereth into the vpper sinus [fig. 5, 2] of the Appendix of the Brace or shin-bone, so the anterior part which is next to the appendix [tab. 24. fig. 1, 3, 7 ab] is rough and full of holes, whereinto the tendons of the Muscles that moue the legge are very strongly inserted.

From hence the Leg-bone is by degrees attenuated, diuersly also distinguished with lines and cauities, and imitateth the forme of a triangular; for it hath one corner like a long and sharpe edge which is situate in the forepart; the second corner is in the Vtter part, the third in the inside; and betwixt these angles the bone lies plaine but lightly excauated, as well to make it more light, as also for the insertion and originall of the Muscles. On the backside it is round.

The anterior part and the middle is produced or lengthened vnto an acute and long angle, [tab. 24. fig. 1 3 γγ] which angle is as sharpe as the edge of a knife, and therefore it is called *spina tibiae*, the spine of the Legge by the best Anatomists.

The second line [tab. 24. fig. 1, 2, 3, 4, 9] which maketh the vtter angle of the backside is also sharpe, and is seated vnder the Brace: this line receiue the Ligament which fastneth the shin and the shank-bones together. ^{His Lines.}

The third line [fig. 1, 2, 3, 4, 11] which maketh the internall angle of the backside is blunt and almost round. Wherefore these lines do make the three sides of the Legge. The first side [fig. 1, 3, 2] is sinuated but plain, and together with the side of the Brace [fig. 1, 5, 2] it affoordeth a place vnto the anterior muscles which descend vnto the foote. The second side [fig. 1, 3 11] is inner and gibbous which by some is called *αντικνημιον*, by some *κνημιν*, in a contrary Sense, because it hath no flesh at all, although the other sides especially behind be very fleshy. The third side [fig. 2, 4, 9] the posterior muscles of the Thigh do occupie, and in it, aboue wee meete with another rough line running obliquely downeward [fig. 2, N] [fig. 4, 2] made for the insertion of the muscle of the Ham.

On the outside aboue the lower head there is also a long sinus which runneth backward, ^{His Sinus.} [tab. 24. fig. 4. 10, 5] which receyueth the interior part of the head of the brace-bone which is a little rough, [Fig. 5, 6, 11, 7] and so the Brace and the Leg or the shin and the shank are ioynd together; but where these bones are conioyned there commeth a strong Ligament betwixt them, which fasteneth them together both in the circumference, and where they touch one another. So also behind it is depressed [Fig. 2, 4, m] and sheweth as it were three sinus which conuay the three Tendons of the fift muscle of the foote, and the two benders of the toes, for these muscles run out vnto the foote.

The lower part of the Legge or the lower head is thicke, which for all the appendix ^{The lower part of the leg.} that is added and the plentifull gristle wherewith it is crufted ouer and made broader is notwithstanding lesser then the vpper, whose Appendix together with the Appendix of the Brace, do make in the surface a large sinus [Fig. 9, defgh] which receiue the *Talus* [tab. 25, Fig. 3, 4, 5, 6] or the Coccalt-bone: but in the appendix of the Leg-bone there is as it were a double sinus [Fig. 9, 10, e f] distinguished by a swelling knot which buncheth lightly in the middest betwixt them. [Fig. 7, 10, d]

It hath also a thicke processe yssuing from the inside, [tab. 24. Fig. 1, 2, 3, 9, 10, i] which processe in that part that regardeth the sinus, [Fig. 9, g] is hollow, smooth and crufted ouer with a gristle whereby the cavity is enlarged, and by that meanes it receyueth the *Talus* more commodiously, for that being inserted into the Sinus it cannot bee moued out of his place. The other side of the processe which regardeth the other Legge is gibbous and without flesh. [Fig. 2, 3, 9, 10 i] But in the opposite part the Legge could not haue had another processe, because it was necessary that in it there should bee a long sinus, into which a part of the Brace-bone was to enter.

This processe is by degrees dilated and determineth into two browes, wherefore also the

eight muscles of the foot are reflected. *rr* 2, 6, 11, a *sinus* of the appendix of the shin-bone from whence goeth a ligament into the instep. *ss* 1, 5, the first line of the shin-bone. *tt* 2, 5, 6, the second line of the shin-bone. *uu* 1, 2, 5, 6, the third line of the shin-bone. *xx* 1, 5, the first side of the shin-bone bunching a little out. *aa* 1, 5, the second side of the shin-bone. *bb* 2, 6, the third side of the shin-bone. *yy* 1, 3, the first line of the Leg-bone. *sss* 1, 2, 3, 4, the second line of the Leg-bone. *ee* 1, 2, 3, 4, the third line of the Leg-bone. *zz* 1, 3, the first side of the Leg-bone. *nn* 1, 3, the second side of the Leg-bone. *θ* 2, 4, the third side of the Leg-bone. *N* 2, 4, a rough line of the third side of the Leg-bone made for the muscle called *Popliteum*.

AB 1, The vpper Appendix of the Leg or shanke-bone.

AB 2, 3, The line where the Appendix ioyneeth with the bone.

C 1, The vpper appendix of the Brace-bone.

C 5, The coniunction of this appendix with the bone.

DD 1, the lower appendix of the Leg-bone.

D 3, the coniunction of this appendix with the bone.

E 1, the lower appendix of the Brace or shinbone.

FG 2, 4, 7, the bosomes of the bones of the Leg receiuing the heads of the thigh bone.

HIK 7, A protuberation which is betwixt these cavities; *KL* in the second, third and fourth figures doe shew the same.

LM 8, a gristle increasing the outward cavity of the Leg-bone *L*, another increasing the inner cavity *M*.

N 8, the foresaide gristles do in this place appeare thickest.

O 8, and here they appeare thinnest.

P 8, here they do determine into sharp points.

Q 5, A shallow *sinus* of the Brace bone to which the head of the leg-bone is articulated.

R 4, the head of the Leg-bone which is ioyned to the Brace.

S 4, 10, A *sinus* of the Leg-bone receiuing the lower end of the Brace bone.

T 5, 6, 11, the inside of the Brace where it is ioyned to the bone of the Leg.

V 2, the context or coniunction of the Brace with the Leg-bone above.

X 2, the same coniunction below.

Y 2, the distance betwixt the shanke & shinbones.

Z 1, 2, The oblique turning of the Brace inward which on the outside is somewhat indented.

ab 1, 3, the forepart of the Leg-bone whereinto the muscles which extend the Leg are inserted.

c 5, 6, the vpper proceffe of the Appendix of the Bracebone, whereinto is inserted the tendon of the fourth muscle of the Legge.

d 5, 6, 9, At this place the vpper part of the *talus* or instep is articulated: in the ninth and tenth figures *d* shew the vpper region; but *d* noteth the protuberation.

h 9, 11, the outside where it is fitted with the instep the inner ankle or a proceffe of the inner appendix of the Legbone.

i 2, 3, 9, 10, the inner alkie.

k 4, 10, a *sinus* of the inner ankle from whence a gristly ligament is inserted into the instep.

l 1, 3, 9, an vnequall *sinus* in the lower appendix of the leg-bone, whence groweth a gristly ligament which is set vnto the necke of the instep.

m 2, 4, 10, certaine *sinus* through which three tendons are led to the foot. *n* 2, 5, 6, 9, the outer ankle or the proceffe of the shin bone in the first figure noted with *E*.

op 1, 5, that part of the shin-bone which is bare. *qq* 2, 6, in this sinuated place of the shin-bone the tendons of the seauenth and

This

the shinne-bone or the *fibula* departeth into a proceffe, that so the bone of the *Talus* might be contained or kept in by both the processe, that it should not slippe out on this side nor on that side. And if at any time the luxation of the *Talus* doe happen, it is rather to the inner processe then to the vtter, because the processe of the *Brace-bone* is lengthned out somewhat longer then the other.

These processees are called *malleoli* the Ankles, the processe of the Legbone is called the inner ankle, and the processe of the *Brace-bone* is called the vtter ankle.

The inner Ankle [figure 1, p. fig. 2, 3, 9, 10, i] in the lower end the backpart hath a rough *sinus* [fig. 4, 10 k] whereout yfflueth a gristly ligament whereby the bone of the leg is fastned to the *Talus*, so likewise in the lower and fore side [fig. 1, 3, 9, i] of the appendix there is a *sinus* rough, transuerse and long, from whence groweth a ligament which fastneth the necke of the *Talus* [ta. 25, fig. 3, N] to the leg-bone.

Finally, this bone as also the *Brace* is notably hollowed within, and that cavity conteyneth the marrow, neither is it without other perforations. The vse of the Leg-bone saith *Archangelus*, is to make the progression more expedite and nimble. And thus much of the Leg or Shank-bone.

Of the Brace or Shin-bone.

The other bone of the Legge is called *fibula*, because as in buildings those Irons whereby the beames and pannes are ioyned together are called *fibula* or *braces*, so this lesser bone may also bee well called the *Brace*, because it ioyneth together the muscles of the Legge: it is also called *cannamini*, and in English if you will the Shin-bone. It is seated on the outside of the Leg as the wand is on the outside of the Cubit; aboue it entreth into a plaine and crufted *sinus* of the Leg-bone [fig. 5, 2] vnder the head thereof [ta. 24, fig. 1, C vnder A] below it entreth into a long *sinus* of the Legge. [Fig. 1, from E to D] At both the ends it is articulated by *Arthrodia* or *adarticulation*, whose motion is obscure. In the midst the two bones doe stand off one from the other [Fig. 2 T betwixt V and X] that so the muscles of the foote might finde place between them especially in the vpper part, because there the Leg is bent into a *sinus*. In this distance there is a membranous ligament which fastneth the skinne and the shanke-bone together. The length of the *Brace-bone* is equall to the length of the other; for although aboue, it do not ascend into the knee, yet belowe it descends lower then the shanke-bone, but in breadth and thickenesse it commeth farre short. Moreouer a little vnder the middest it is somewhat curued toward the Legbone, and the outside is after a sort concauous, [Fig. 1, 2, Z] yea to say true, the figure of it is not much vnlike the figure of the Leg-bone it selfe.

It hath two heades, one aboue and another below whereto there groweth an Appendix which endeth into an acute processe somewhat exasperated. The vpper of these is below the head of the shanke-bone, [Fig. 1, C vnder A] which is defended with an Appendix and crufted ouer with a gristle: it is round, and on the outside swelleth very notably, [Fig. 5, b c] the better to receiue the tendon of the fourth muscle of the Legge, as also to giue an originall vnto the head of the seauenth muscle of the foote. The Appendix of this head hath on the inside a large and ample *sinus* [Fig. 5, Q] crufted ouer with a gristle whereto the head of the Appendix of the Leg-bone is articulated [Fig. 4, P.]

The lower head tendeth into a sharpnesse [fig. 1, E] and descendeth so much lower then the Leg-bone, as the head of the leg-bone ascended aboue the *Brace* in the top; it is also furnished with one appendix [Fig. 1, E 2, 5, 6, 9, n] which growing thick departeth with a processe called the outward ankle, which descendeth somewhat lower then the inner ankle and maketh the externall side [Fig. 9, 11. h] of the common *sinus* [Fig. 7, defgh] which receiue the *Talus* or bone of the instep, and is crufted ouer with a gristle. This ankle is lower then the inner, and on the outside gibbous, some part of it also may bee felt without flesh, and from it some muscles of the foote (properly so called) take their originall; on the inside it hath a rough *sinus* [Fig. 2, 6, 11, r] out of which ariseth the gristly Ligament which fastneth the *Brace* or shin-bone to the instep. Aboue the Ankle there is a *sinus* [f. 2, 6, q] couered with a transuerse Ligament; where vnder the tendons of the sixt and seauenth muscles of the foote are safely conuayed.

Betwixt these two heades of the body the *Brace* or shin-bone is vnequall, because of cauities and lines therein made for the insertion of muscles: so that about the middle it seemeth to be triangular; for before there appeareth an acute and swelling line, [f. 1, 2, ff] behind it is depressed and hath on either hand a strutting line, [fig. 1, 2, 5, 6. ttvv] and these lines

lines make the three sides of the *Brace-bone*. [fig. 1, 5, 2, 6. ^β] In like manner at the lower end about the appendix [fig. 5, 6, 117] there buncheth out an asperity, at which place by the interposition of a ligament it is fastned to the shanke or leg-bone:

The vse of it.

The vse of the *Brace-bone* is threefold: the first to ioyne the Leg and the Instep, whereby the foote is bent and extended: secondly to defend the vessels and muscles of the Leg from outward iniuries, for the *Brace-bone* couereth for the most part the course of them all. Thirdly, to sustaine, strengthen and secure the Legge by fastening it to the outward head of the Thigh-bone. Moreouer, as the Wand helpeth to moue the Hand, so the *Brace-bone* helpeth to moue the Foot in compasse, saith *Archangelus*.

CHAP. XXXV.

Of the whirle-bone of the Knee.

The names of the whirle-bone.

Efore wee part from the Leg, you must remember that there is a bone placed before the ioynt of the Knee [tab. 23, fig. 4: and 5,] which the Grecians call *ἐμπροσθεν* and *ἐμπροσθεν*, because it lieth vpon the Knee; others call it *μύλον*, the Millstone, because it is very like it. *Celsus* calleth it *patella* or the *Sawcer*. It is also very commonly called *Rotula*, we will call it the Whirle-bone.

How it is fastned.

It is a bone common to the Thigh and the Leg although it be separated from them both, for it is placed before their articulation. In each knee there is one, somewhat round and broad and ending into a sharpnesse where it resteth vpon the Leg. The magnitude of it is moderate, the latitude scarce two fingers broad, the longitude is somewhat thereabouts, the thicknesse is vnequall, for in the extremities it is thinne and growes thicker by degrees, so that in the middest it buncheth out like a compassed buckler, or if you will, like an embowed Looking-glasse such as they vsed in ancient times. The vpper part thereof groweth to the thicke Tendons of the seauenth, eight and ninth muscles of the Thigh, which by the knee doe runne vnto the Leg: by these Tendons it is established, for they serue it in steade of a Ligament to fasten it both to the Thigh and to the Leg: moreouer on the outside it is couered by them; on the inside it is cruisted ouer with a smooth and slippery gristle, at least the greatest part of it, especially where it regardeth the Thigh, and this gristle maketh the motion more glib, for it will easily moue vnder a mans finger. *Columbus* cannot taste this conceit, but sayeth that it is fastened both to the Thigh and to the Leg by Ligaments of his owne, which sayeth hee doe grow from the *Appendices* of the Thigh and the Legge, so also sayth *Archangelus*, yet he doth not deny but it is established by the Tendons of the muscles before spoken of. But *Bauhine* leaneth more to the first opinion of *Vesalius*, that it hath no other Ligaments but the Tendons. If these Tendons to which it groweth be cunningly taken away, it will appeare both before and in the sides [tab. 24, fig. 4] rough and full of blind holes, but behinde it hath a moderate protuberation [fig. 5, gh] and shallow bosome on either side [fig. 5, ik] cruisted ouer with a gristle, of which the vtter is the larger and the broader.

His articulation.

This protuberation wee speake of, is receiued by the *sinus* which is betwixt the heads of the Thigh, [fr. 1, A betwixt EF] like as the bosome of this whirlebone receiueth the heads of the Thigh, wherefore the Thigh receiueth the whirle and the whirle the Thigh, and so are ioyned by *Ginglymos*; but the whirle and the Leg-bone are ioyned by *adarticulation*: wherefore it is mouable least it should make the motion of that ioynt difficile or hard. Moreouer the inner and lower part [fig. 5, L] where it groweth into a proceffe and regardeth the vpper part of the Legge-bone, is rough and perforated, that it might growe the faster to the Tendons of the foresaid muscles.

The substance of the whirle is at the first gristly and so remayneth for certaine months. Afterward it groweth as hard as a hard Appendix, and at length bony, hard and solid, such as it appeareth in growne bodies, so saith *Falopius* in his obseruations, and with him *Bauhine* consenteth; *Columbus* thinketh it groweth not beyonde the height of an hard Appendix.

The vse of it is to couer and to firme the lax and dissolute composition of the ioynt of the Thigh and the Leg, least in progression and walking the Thigh shall luxe outward, as also when we goe downe a hill it might support the ioynt. Moreouer, by the helpe of the whirle when the knee is gathered directly backward, it is bent into a right angle.

Finally

Finally, it defendeth the Tendons of the foresaid muscles, least in the bending of the knee when the thigh bone presseth forward it should beare too hard vpon them; and in a word as the Seede-bones of which we spake before, the hardnesse of it receiuerh the violence of the Thigh-bone, and breaketh it that it should not compresse those Tendons.

CHAP. XXXVI.

Of the bones of the foote properly so called, and particularly
of the Wrest of the Foote.

WE are now come vnto the third and last part of the Foote, which is properly called the Foot, and *Pes extremus* or *Pes parvus*. It hath 38 bones and three parts. The first part is called *Tarsus*, which we call the wrest of the Foote: and hath seuen bones.

The second is called *metatarsus* or *pedium*. the Afterwrest of the Foot, and hath five bones.

The third part is of the Toes, which haue foureteene bones, to which we may adde twelue Seed-bones. Of these in order.

Of the seuen bones of the *Tarsus* or wrest of the Foot: foure haue names, the other three are not so much beholding yet vnto Anatomists.

The first [ta. 25, fi. 1 and 2. and the whole third, fourth fift, and sixth figures] which the Grecians call ἀσπίς, and ἄσπις, the Latines *Os balista* and *Talus*. The pasterne bone lyeth vnder the *Appendices* of the shinne and shanke-bones as a firme and stable foundation, and yet it seemeth to lye onely vnder the shanke, and this bone is not onely found in men but in all other creatures whose feet are diuided into Toes. In the vpper part thereof there is a smooth and round knub [fig. 3, 4, 6, ABCD] crufted ouer with a gristle, which representeth the forme of the nut of a Crosse-bow. The surface also of the knot is as it were foure square, limited about the edges, with foure sides, and therefore by some is called *quatrio*: the first and second of these [fig. 3, 5, 6, from A to B and from C to D] goe through his length: the third is on the fore side [from A to C] the fourth on the back side. [from C to D] In the middle it hath a shallow cavity [fi. 3. EE] with rising sides [fi. 3. FF] like the sides of the furrow of a pulley wherein the rope runneth, by which *sinus* it is coupled be *Ginglymos* with the appendix of the shank-bone. [ta. 24, fi. 9, 10, def] The sides of it are plaine and sloping, crufted ouer with a thinn gristle to receiue the Ankles: the inside [fi. 5, G] is crufted but a little way, and receiues the inner Ankle of the Leg; the outside is broader [fi. 6. H] and more hollowed, descending lower the better to admit the outward ankle of the Brace-bone which also descendeth lower. [tab. 24, fi. 9, 1, 1, b] And thus the *Talus* is ioyned with the Leg and the Brace, which articulation serueth for the right motion of the foote, which that it might more easily performe and without attrition of the bones, it is on both hands crufted ouer with a gristle.

The first bone
of the *Tarsus*.

Furthermore, on the inside it hath a rough *sinus* [fig. 5, I] whereinto a gristly Ligament is receiued which groweth from the inner ankle, and whereby the *Talus* is fastned to the shank. Againe, on the outside [fig. 6, R] there is another *sinus* which receiuerh a Ligament produced from the outward ankle. Moreover, on the back side at the root of the protuberation where it is ioyned to the Leg and the heele [fig. 5, after BD] there is a roughnesse, partly to receiue the ligaments which grow from the Leg, partly to reach other ligaments vnto the heele. There is also in the back part [fig. 5, 6, LM] a *sinus* prepared for the transition of the tendons of muscles which attaine to the sole of the foote.

Yet further, this first bone is not onely ioyned with the shinne and the shanke, but also with the *Boate-bone*, and therefore the forepart of the *Talus* is lengthned into a long necke, [fig. 3, 4, 5, 6 N] and the necke endeth into a round head [O] couered ouer with a slippery gristle which is receiued by the large and round *sinus* or bosome [fig. 11, K] of the *boate-bone*, and by the meanes hereof the foote is moderately and with an oblique motion moued inward and outward, and something also in compasse.

At the Heele also this *pasterne-bone* is fastned with a double ioynt, and therefore the lower part thereof hath on the back side a large and deepe *sinus* [figure 4, 2] couered ouer with a gristle, into which the large and broad head [figure 7, 8, 9, P] of the heele-bone is inserted: before it hath a long and smooth protuberation [figure 4, S] which is receiued by a long bosome [Figure 7, 8, 9, R] on the back side of the heele. Betwixt these two spaces or in

the

the middle of these ioynts there is a deepe and rough cavity [fi. 4, TT] whereto the sinus of the heele [fig. 7. 8. 9 R] is opposite and answerable; the vse of which cavity is to containe a mucous substance and fat withall, whereby these bones are moystened that they should not grow dry by perpetuall motion. Moreover in the same cavity doe grow these gristly ligaments which in this place doe very strongly binde the pasterne bone to the heele, and therefore when the bones are cleansed and afterward fastened together, there remaineth in this place a great distance. Sometime also on the backside it is extended above the heele where it bends inward as it were into a double small proesse. It hath no appendix, for it hath need of equall strength on euery side; neither receiuerh it the insertion of muscles, neither doth it offer originall vnto them.

The substance of this bone in the originall, as also of all the other bones of the wrist of the foote excepting the heele is a gristle, but in growne bodies it is on the inside fungous, yet where the proesses breake forth, solid and dense, saving that it is perforated manifold.

The second
bone of the
wrist.
The heele.

The second bone of the wrist [fig. 1, and 2, and the whole seven, eight and nine figures] is called in Greeke *καλκάνιον*, *Calx*, *calcaneum*, *pedis calcx*, in English the Heele. This is the greatest and the thickest bone of the whole foot properly so called, and was so made for more strength and firmitude. For the extension and flexion of the foote are made by the articulation of the *Talus* or pasterne bone to the bones of the Leg and the brace. Again, the motion of the foote to the sides, is wrought by the coniunction of the *Talus* to the boat-bone; the rest of the connexions of the Bones which are many and small doe little assist the former.

His vse.

As therefore the *Talus* or pasterne bone is the principall agent in the motions of the foot, so is the heele the principall firmer and establisher thereof. And vnlesse the heele had beene greater then the *Talus*, not onely the pasterne it selfe, but the shanke also would slip backward, for it lyeth directly vnder the shanke and almost alone supporteth it, and by it the Thigh, and by the Thigh the whole body. It was therefore very necessary that it should be a notable large bone, or else Nature had beene very improuident to lay so great a weight vpon it. It behoued also that his articulation should be very firme, not wauering or vnstedfast, and therefore Nature ioynd his proesses with many hard, gristly, broad and round ligaments, not onely to the pasterne bone but also to other bones neare adioyning to make his strength more assured. Wherefore it doth not onely lye vnder the *Talus* and sustaine it, but is also articulated thereto and to the cube. To the *Talus* the vpper part of his large head [Figure 6, 8, 9 P] entring into the sinus of the *Talus* [Figure 4, 2] and againe the heele admitteth into a narrow and almost plaine sinus of his owne [Figure 7, 8, 9, R] the protuberation of the *Talus*: [Figure 9, S] to the Cube-bone it is ioynd on the fore side [Fig. 11 R] by his depressed head. [Figure 7, 2]

The lower part of the Heele [Fig. 2, XYZ] is somewhat broad that the foote might stand more safely; rough also and vnequall because of the muscles. It hath a rough [Fi. 2, y x Fig. 8, y Fig. 9, z] and transuerse proesse running from behind downward, from whose fore side ariseth the muscle which bendeth the second bones of the foure Toes, and the fleshy portion, from which are produced the muscles which leade the foure Toes to the great Toe: wherefore within the proesse there is a cavity least when the foot is fastened vpon the ground, the heads of these muscles should be compressed.

The head of the heele or the vpper part thereof in children hath an Appendix, and is like a round body, hauing a light impression raised with a little ruggednesse [figure 7. 8, 9. ab] into which impression the Ligaments of the shanke bone and of the pasterne are inserted. On the backside this vpper part is depressed and rough on either hand, [Fig. 2, 8, 9, c] in which depression and asperity the greatest and strongest tendon of the whole body, that is, of the first, second and fourth muscles of the foote is inserted. On the fore side it hath rough and deepe bosomes, [Figure 7, V V] which with the bosomes of the pasterne are filled with gristles.

The sides of the heele are broad and depressed. The inside [Figure 2, 8, dd] is smooth and notably sinewated; in the middle are three inscriptions [Figure 2, 8, e] to make way for the tendons of the fifth muscle of the foote, and the two benders of the last ioynts, which passe that way vnto the sole of the foote: that way also passe the veines, arteries and nerues, which are also defended by the proesse of the heele which maketh the inside of the heele very deepe.

The

Table 25. Sheweth the bones of the Foote properly so called.

Fig. 1, and 2, shew the bones of the right foote fastened together their upper face and their neather face.

Fig. 3, 4, 5, & 6, shew the upper, lower, inner & outer sides of the Talus or pasterne.

Fig. 7, 8, 9, sheweth the same sides of the Heele.

Fig. 10, and 11, sheweth the forward and backward side of the boate-bone.

Fig. 12, and 13, shew the fore and backpart of the wrist made of foure bones.

TABVLA. XXV.

ABCD 3, 5, 6. The protuberation of the Talus ioyned to the appendix of the leg-bone, and of this protuberation foure sides.

EE 3, A sinus insculped in the protuberation of the Talus.

FF 3, two bunching parts of the protuberation of the Talus.

G 3, the inner side of the protuberation of the Talus crusted ouer with a gristle, ioyned to the inner ankle.

H 6. The outward sinus of the protuberation of the Talus couered ouer with a gristle, and receiuing the inner ankle.

I 5, a rough sinus of the Talus receiuing a gristly ligament from the inner ankle.

K, 6, a sinus of the Talus receiuing a gristly ligament from the outward ankle.

L M 5, 6, two sinus in the hinder part of the Talus.

N 3, 4, 5, 6, the necke of the Talus or pastern bone.

O 3, 4, 5, 6, the head of the Talus going vnder the sinus of the boate bone.

P 7, 8, 9, the head of the bone of the heele crusted ouer with a gristle and going vnder the sinus of the Talus or the pasterne bone.

Q, 4, a large sinus of the Talus receiuing the head of the heele.

R 7, 8, 9, a sinus of the heele whereto the lower part of the head of the Talus is ioyned.

S 4, the lower part of the head of the Talus going into the sinus of the heele.

TT 4, a sharpe sinus of the heele receiuing a gristly ligament from the pasterne bone.

XX 2, the place of the heele.

YZ 2, Y 8, Z 9, a proceffe of the heele made for the production of muscles.

ab 7, 8, 9, from a to b the distance of the vpper part of the heele.

c 8, 9, the hinder part of the heele.

d 2, 8, the inner side of the heele.

e 8, the place where the tendons that run to the bottom of the foote are reflected.

f 7, 8, the viter side of the heele.

g 1, 7, 9, here the tendons of the 7 and 8 muscles of the foote are stretched out.

b 7, the forepart of the heele which is ioyned to the pasterne bone.

7, that part of the heele which is ioyned to the Cube bone.

k 1, the sinus of the Boat-bone receiuing the head of the Talus.

lmn 10, three surfaces of the Boat-bone lightly prominent, which are articulated to the bones of the wrist.

op 11, the vpper part of the Boatbone regarding the top of the foot. q r 10, and q 11, his lower part. q 10, 11, A sinus through which the sixt muscle of the foote is led. s t u 13, the plaine surfaces of the three inner bones of the wrist whereby they are articulated to the Boat-bone. x 13, a shallow sinus of the Cube bone whereby it is articulated to the heele, ab 12, the place of the Cube bone to which that bone of the Afterwrist is ioyned which supporteth the last Toe saue one. y 12, 13, the place of the Cube bone where the third bone of the wrist is articulated, a 12, 13, that part of the Cube bone which respecteth the outside of the foote. e 12, 13 the surface of the Cube-bone in the vpper part of the foote. f 2, 13, that part of the Cube bone which regardeth the earth, u 2, a sinus of the Cube-bone at which the tendon of the seuenth muscle of the foot is reflected. B 13, a proceffe of the third bone of the wrist wherinto the fift muscle of the foot is inserted, i 12, the place of the inner bone of the wrist to which that bone of the Afterwrist which sustaineth the great Toe is coupled. x 12, the place of the second bone of the wrist whereto the bone of the Afterwrist that supporteth the fore Toe is articulated. a 12, the place of the third bone of the wrist whereto that bone of the Afterwrist which supporteth the middle toe is articulated. u 1, 2, a small bone whereby that bone of the Afterwrist which sustaineth the little toe is ioyned vnto the Cube bone. vv 1, 2 the distances betwixt the bones of the Afterwrist. xz 1, 2, the heads of the bones of the Afterwrist which enter into the bosomes of the toes. π, 2, a proceffe of the bone of the afterwrist whereinto the tendon of the seuenth muscle of the foote is implanted. p 2, a proceffe of the Bone of the Afterwrist, which sustaineth the little toe, which proceffe receiue the tendon of the eight muscle of the foot. s, t, u, 1, 2, the three bones of the

the foretoe. 2, two seede bones placed vnder that bone of the Afterwrest which sustaineth the great toe, * 2 vnder X. a seede bone set to the second ioynt of the great Toe. F. 1, 2, the *Talus* or pasterne. Δ. 1, 2 the Heele. Θ. 1, 2, the Boat-bone. Λ, Z. 1, 2, the bones of the toes. ϕ, X. 1, 2, two bones of the great toe. I, II, III, IV, V, 1 the five bones of the Afterwrest, 1, 2, 3, 4. in fig. 1, 2, 12, 13, the four bones of the *Tarsus* or the Wrest. Ch. 1, in fig. 12 and 13, the greater wedgbone or the first bone of the wrest. Ch. 2, fig. 12, 13, the lesser wedge bone or sixth bone of the wrest. Cha. 3, fig. 12, 13 the middle wedgbone, or the seventh bone of the wrest, Cha. 4 fig. 12, 13, the Cube-bone.

The outside [fig. 2, 9 Z] is depressed, rough and vnequall, out of whose lower part yssueth the muscle which leadeth the little Toe from the rest, but in the foreside there is a little sinus [fig. 1, 7, 9 S] crufted ouer with a Gristle, which we meet withall vnder a small proceffe, and through this sinus the tendons of the seventh and eight muscles of the sole do passe and are reflected vnto the backside of the vtter ankle. That part of the heele that is next the little Toe is on the foreside smooth by reason of a gristle wherewith it is crufted ouer, and the vpper part shooteth out a large head raised somewhat high, by which head the heele is articulated into a sinus of the Cube-bone almost plaine, [fig. 1, 2, Θ] below it hath an oblique Sinus bending inward, which receiueth a part of the Cube-bone.

The third bone of the wrest [fig. 10, 11,] is called by the Grecians *σκαφοειδής*, *Nauforme*, *Os Naucular*, *Cymba* the Boat-bone, because it is long, deepe, behind hollow, before and in the vpper part gibbous, [fig. 1, op] in the lower part hollow, [fi. 10, 11 q] This *Boat-bone* is seated in the inside of the foot, and by the mediation therof, the greatest part of the wrest is ioyned to the *Talus*. For on the backward it hath a Sinus [fi. 11, k] deepe and transuersely long, [fi. 1, olmn] in which the head of the *Talus* [fi. 3, 4, 5, O] is inserted, and this articulation must be referred to an obscure *Enarthrosis* or *Inarticulation*, because the motion therof is obscure. The other part hath a long head bunching out, and distinguished with a threefold superficies or surface [fig. 10, lmn] to which the three last bones are articulated, [fig. 1, 2, 12, 13, cha. 1, 2 3,] but because they are very smooth, it is to be doubted whether they receive or are received.

The outside of this Boat-bone is large, round and sinuated [fig. 10, qr and 11 q] especially where it is ioyned to the first bone. Presently after, it is angustated by degrees, and endeth into an internall narrow proceffe [fig. 10, q] resembling the prow of a ship. The inside is prominent, so that it maketh a notable protuberation, which protuberation maketh the lower sinus [fig. 10, 11, q] ouer which it hangeth much greater where the tendon of the first muscle of the foote is reflected. Finally this Boat-bone is rough about and below, that from thence the ligaments might yssue which tye this bone to the *Talus*, and the bones the of wrest of the foote.

These three bones whereto there is nothing answerable in the hand, and are as it were the basis of the leg, the Ancients haue not numbred among the bones of the wrest of the foot. There follow other foure, which (say they) do alone make the *tarsus* or wrest, and are like vnto the wrest of the hand; for being ioyned together by Ligaments, they make as it were an Arch, whose vpper superficies is conuexe, and the lowes concavous or hollow: for the Cube-bone is ioyned to the heele, and the three following to the Boat-bone, and with them are together lifted vp from the earth, for such a construction as this is stronger both for the fastening of the foot and sustaining of the body, for an arched building is more strong and lasting. These bones also were necessarily prominent, that vnder such prominences a cavity should be left, wherein as well the tendons of those muscles should be secured which runne vnder the sole, as also the muscles themselves which arise from the lower part of the wrest, and are directed to the toes of the foote; for if the sole had been plaine, the Muscles with their tendons would haue been compressed, and so neither could a man haue travelled without paine, and besides the muscles had been kept from performing their office in flexion and extension.

Moreouer, where these bones are ioyned one to the sides of another, they are not couered ouer with gristles, sauing onely where they beare vpon the Boat-bone. Otherwhere they are coupled with gristly Ligaments. They are also without *Appendices*, and their substance is like the substance of the pasterne and Boat-bones. They differ also in quantity and figure, [conferre Fig. 1 with 2, and 12 with 13] for the two first are far greater then those two in the middest, and are ioyned to the foure bones of the *Pedum* or Afterwrest, but we will intreat of them particularly.

The fourth bone of the wrest [fig. 12, 13, cha. 4] is called in Greeke *κυβοειδής*, *Os Cubiforme* from the forme of a Dye, because it hath as it were six sides. It is also called *πολυμύρρον*, *Os*

The third
bone of the
Wrest.

The fourth
bone.

Os Multiforme, because it hath diuers formes. This bone on the outside of the foot is placed before the heele. It is greater then the rest and the first side of it [fig. 13, x] is ioyned behind to the heele [fig. 7, i] with an vnequall surface and resteth vpon the ground, and it is doubtful whether it receiue or be receiued. *Archangelus* affirmeth both: the second side, [fig. 12, a, b] before is ioyned with a continual superficies to the fourth and fift bones of the Afterwrest, and supporteth them like a basis; the third side is inward [fig. 12, 13, y] and articulated to the seventh bone of the wrist; the fourth side is outward [figure 12, 13, d] and obscurely plaine, neither doth it ioine to any bone, no more then the two following sides doe, for the fift side is aboue plaine and rough [figure 12, 13, e] and the sixt is below. [figure 2, 3, figure 3, c] Finally, the latter end or extremity of it hath a proceffe diuided by a middle sinus, [fig. 2, n] which is long and oblique, whereat the tendon of the seventh muscle of the foot is resolved.

The fift bone of the wrist [fig. 12, cha. 1, fig. 13, f] as also the two following, are called in Greeke *χαλκοειδής*, *Cuneiformia*, because they are like wedges. This fift occupyeth the inside of the foote, and is seated ouer against the great toe. On the foreside it is sinuated [fig. 13, y] to receiue a portion of the proceffe of the Boat-bone: behind, it receiueth the first bone of the *Pedium* or Afterwrest, and it is vncertaine whether it be sinewated or prominent, which vncertainty is common to the backward bones, as they are coupled either one with another, or with the bones of the Afterwrest, so that they seeme to be conioyned by *Ginglymos*, because they haue obscure Sinus or bosomes, notwithstanding this part seemeth to haue two smal knots or protuberations, because the bone of the Afterwrest carrieth the shew of a double cavity: the vpper part is but small and a little conuex, whereby it is ioyned to a shallow or superficially Sinus of the sixt bone; the lower side is thicker, that it might rest faster vpon the ground.

The sixt bone of the wrist [fig. 12, 13, ch. 2, 7] is called *Cuneiforme minus*, the lesser wedge, and if you regard the vpper part which looketh toward the foote it is broad, somewhat arched, and as it were foure cornered. If you respect the lower part which looketh toward the foote it is very narrow and edged, and so resembleth a wedge, as also doth the seventh which is next vnto it, for they both seeme to be like wedges interposed amongst the rest to ioine them the faster together. This sixt bone behind is ioyned to the Boat-bone; [fig. 13, f] before it lightly buncheth out and it fastened to the second bone of the Afterwrest; [fig. 12, x] on the inside it is ioyned with the outside of the fift bone of the wrist, and on the outside with the outside of the seventh.

The seventh bone of the wrist [fig. 12 and 13, cha. 3, 1] is called *Cuneiforme medium*, the middle wedge, and is seated betwixt the fourth and the sixt. It is somewhat like a Quadrangle but longer, for on the backside it hath a small sinus [fig. 13, u] which receiueth the protuberation of the Boat-bone; on the foreside it admitteth the third bone of the Afterwrest, [fig. 12, y] and the sides of it touch the sides of the sixt and the fourth Bones. And thus it is placed amongst the bones like a wedge; below it swelleth out with a protuberation, [fig. 13, o] whereinto the fift muscle of the foote is inserted.

[The twelfth Figure sheweth the anterior face of the foure bones of the wrist, of the foote fastened together, the thirteenth figure sheweth their backside.]

CHAP. XXXVII.

Of the Bones of the Afterwrest, and the Toes of the Feet.

THE second part of the Foote is called *medior*, by the Grecians, by *Celsus Planta*, the tread of the Foot, by others *peden*, and by others *Metatarsum*, because it is answerable to the *Metacarpium* in the hand, we will call it the *Afterwrest of the Foote*. [tabl. 15, fig. 1, ch. I, II, III, IV, V] It is compounded of five bones which are articulated to the Bones of the *Tarsus* or wrist, and do sustaine the bones of the Toes. To the *Tarsus* or wrist they are ioyned by a somewhat plaine and smooth superficies [fig. 12, 2, x, y, a, b.]

The first which is placed before the great toe, is articulated to the inner bone of the wrist; that which is placed before the next to the great toe is ioyned to the second bone of the wrist; that which is placed before the middle toe to the third, [figure 2 betwixt, w] the other two are articulated to the Cube-bone. [figure 2 neere p and n] And as the bones of the Wrist of the foote are not placed on the foreside in a right line, so of the bones

The fift bone.

The sixt bone.

The seventh bone.

The afterwrist of the Foot.

bones of the Afterwrest one enclineth more backward then another. Notwithstanding, they stand in one order or ranke as do the bones of the Toes, which maketh much to stability and firmitude.

They are long bones and round, and end on both sides into heads. For where they are articulated with the bones of the wrest they are thicke and sinewated and ioyned together by their sides; where they recede, or depart by degrees one from another, they become slender and leaue a distance between them for the Muscles called *Interossei*, which we called the *Bone-bound Muscles*. But their lower heads which are inserted into the deepe bosomes of the first ioyns of the Toes [fig. 1, 2, & in ^o] are orbicular, and on the backside encreased with an Appendix. The heads of these bones are more diuided towards the vpper part and lesse toward the lower, quite contrary to that it is in the hands, and the reason was because in extension it behoued that the toes of the feet should be more eleuated then the fingers of the hand, which kind of articulation we call *Enarthrosis* or *Inarticulation*.

The first.

The first of these that is set before the great toe, is the thickest of them all and the shortest, hauing a rounder head, that so the great toe might be better moued to the sides then any of the rest. In the lower part vnder the head, where it is articulated with the *Tarsus* or wrest it buncheth out into a proesse [fig. 2 ^o] whereinto is inserted the tendon of the seuenth muscle of the foote, and at the same place there are two Seede-bones greater then the rest, and crufted ouer with a gristle.

The second bone of the Afterwrest which sustaineth the foretoe is the longest, vnlesse it be the fift which sustaineth the little toe; for the length of this last is encreased by a notable proesse, [fig. 2, ^o] whereby it was articulated to the wrest, because it was to be lengthned into the outside of the foot to make a place of implantation for the tendon of the eight muscle of the foot. These bones of the Afterwrest aboue and below, haue *Appendices* crufted ouer with gristles; their substance also and their cavity which containeth their marrow is answerable to the substance and cavity of the bones of the Afterwrest of the Hand. Moreover they are thrilled with small holes, by which little veines and arteries, as in other bones, do passe in to nourish and cherish them.

The bones of the Toes.

After the bones of the Afterwrest do follow the bones of the toes which make the third part of the foot and are in number fourteen [fig. 1 A, fig. 2 A, B] for euery one of them consisteth of three bones, as it is in the fingers of the hand excepting the great toe; [fig. 1, 2, 5, 7, v.] and indeed their substance, structure and situation is little different from the hand, sauing that the first ioyns haue a deeper sinus because the deeper heads of the bones of the *Pedum* or Afterwrest are inserted into them. And although the heads of the bones of the foot are larger yet is not their sinus so large as in the hands, that so in extension the toes might be more lifted vp, and yeeld something to the ground vpon which we stand. The great toe is formed of two bones [fig. 1, ^o, x.] that the foreside of the cavity of the Afterwrest might more firmly rest vpon the earth. All these Bones aboue and below haue *Appendices*, and are crufted ouer with strong gristles to make the ioyn more glib which is articulated by *Ginglymos*, alwaies excepting the last bones of the toes, which are not articulated to any other bone, but haue nayles cleaving vnto them. Note also, that the knuckles of the toes are shorter then those of the hands, gibbous aboue and hollow below; the better to admit the Tendons of the muscles which bend the second and third ioyns. Againe, the first bones are greater then the second, and the second greater then the third, and the middle bone in foure toes seemeth to bee square. In like manner, the bones of the great toe are thicker then the bones of the thumbe: the rest of the bones of the toes are lesser then the bones of the fingers. Finally, the bones of the toes are also full of marrow.

CHAP. XXXVIII.

Of the Seed-bones and the Nayles.

THE Seed-bones [ta. 25. fig. 2, 4, 5] are of the same number and position with the Seed-bones in the hands, that is to say twelue, and they are so much lesse and lesse conspicuous in the toes then they are in the fingers; as the fingers are greater then the toes: notwithstanding as the great toe hath greater bones then the thumbe, so also are his seed bones larger. Wherefore at the first ioyn of the great toe neere the head of the bone of the Afterwrest which is articulated to that ioyn, there are two notable seed-bones which lye vnder the neruous part of the muscle which bendeth the first bone of the great toe: and

and of these the inner is bigger almost by halfe then the other, yea as big as halfe a great pease when the husk is off, and not much vnlike it. This bone the Arabians call *Albadara*, and they say (how foolishly let the Diuines speake) that of this bone as it were of seed a man receiueth the new body wherewith he riseth at the resurrection; that which lyeth vnder the second ioynt of the great toe and is much lesse then the former, leaneth vpon the tendon of the muscle which bendeth the second bone of the great toe.

Concerning the rest of the seedbones, they are disposed as is said in the history of the hand.

To this place we thought good to refer two smal bones found in the Ham neere the thigh-bone, and growing to the heads of the two first muscles which moue the Foote. These bones, saith *Vesalius*, are found in Harts, in Dogs, and Hares, and such like dry creatures, yea in old men also: Their surface is slippery and regardeth the vpper part of the lower heads of the thigh, to which bones this is peculiar, that they do not leane vpon the tendons of the muscles as other seedbones doe, but vpon their originals, like as doth the bony part which in old men is fastned to the Cube-bone, which bony part we meet withall in the tendon of the seventh muscle of the foote there reflected.

Furthermore, as we said before, that to the outside of the ioynt, whereat the bone of the Afterwrest which sustaineth the little finger is fastned to the wrest, there is a small bone annexed, so also in the foote at the ourside of the articulation of that bone of the Afterwrest of the foote which supporteth the little toe [14.25. f. 1, 2, 14] where the fist bone of the Afterwrest is articulated to the Cube-bone, there is also found a small bone at the insertion of the tendon of the eight muscle of the foot.

These seed-bones, although they seeme to haue the same vse that they haue in the hands: yet morrouer in the foot they are the cause why when we stand or walke, whether the place be rough or smooth, the foot applies it selfe more equally vnto the earth: as also to keepe the toes when we stand or walke, from being luxed by stones or any other eminent thing we should light vpon. Finally, the extremities or ends of the toes (as it is in the Fingers) are couered and defended with nayles fastned to the skin on the outside, of which we will adde a few words. The Nayles are called by the Grecians *ὀνυχες*, their roote *ρίζονυχας*, the bottome or white moone *ἀνταπλῆ*, and the filme that groweth to the roote *ἀρχιμῶν*. There are diuers opinions concerning the matter of the Nails: some thinke, it is a glutinous moysture parched and dried by the heate, and driuen vnto the extreame parts, and therefore saith *Hippocrates*, are the nails exceeding fast and thight, because their matter is baked together. Secondly *Empedocles* conceiueth, that the nails were made of nerues by congelation, and therefore *Pæsius* in his notes vpon *Hippocrates* calls the nails *Nervorum clausulas summas*, the terminations of the nerues giuen by Nature to make vp and establish the extremities of the body, and therefore if they faile or fall away it is a signe of great weakenesse. Thirdly *Aristotle* in the sixt chapter of his 2 booke *de generatione animal*, saith, that the nails, the haire, hornes, beakes of birds, hooues and such like are engendred of aduentitious aliment. Fourthly *Columbus* remembers, that some thinke the nails are amassed of a part of a bone of a nerue of skin (yea some say also) of flesh, but he doth not easily subscribe to their conceite.

Columbus saith, they take their originall partly from the skin, partly from the tendons of the muscles which extend the Fingers and the toes. *Bauhine* saith, that some conceiue them to arise from the crasse excrements of the third concoction, and therefore that they continually grow by an imperfect accretion, made by the Apposition onely or addition of Aliment, whence (say they) it is that they grow onely in length, not in bredth or depth, and therefore are to be excluded out of the number of liuing parts; notwithstanding *Galen* in his booke *de Admin. Anatom.* witnesseth, that there is conveyed to the roots of the nails, a veine, an artery and a nerue, by which they receiue aliment, life and sense, as other parts doe. And truly, two Nerues are not onely conveyed vnto the roots of the nails, but also doe creepe vnder the nails together with the veines vnto the very top of the Finger, yet we do not say that the nails haue sense, because these nerues are not distributed throughout the substance of the nails no more then are the veines which vnburthen themselves of the Aliment at the roots of the naile. We conclude therefore that the nails are encreased like the teeth by an Apposition of aliment to their roote, which was the best way, because they were euery day worn, and therefore had more neede to be restored in their length then in their bredth and thicknesse.

Their substance is of a middle Nature betwixt bones and gristles moderately hard, the better to beare the violence of outward iniuries, flexible or buxome that they should not breake

Albadara,

ions of their
generation

Their substance
is

but giue way to violence; pellucide or transparent and therefore they are either red or liuid according to their flesh vnder them: thin they are and conuex, that they might lye more snugly vpon the fingers, and this also maketh much for their security; for if they stood off from the flesh they would easily be torne from their roots. Againe, to make them more steadfast, they are fastned at their root with a Ligament, and because they must needs grow to the flesh and the skin, therefore the skin on the outside compasseth the root round, but the flesh groweth to them more inward. Vnder the nayles, as far as to the very extremities or ends of the fingers the tendons of muscles doe passe and are dilated vnder them, which thing, saith *Columbus*, I first obserued. And this is the reason why the part vnder them is of so exquisite sence, and the paine so great if any sharpe splinter or such like doe get vnder the naile.

Their vse.

The vse of the nayles is to defend the end of the fingers which are very soft, that they be not offended by outward occurrents; their hardnesse therefore giues a firmitude vnto the softnesse of the flesh. Againe, the hands had nayles for better apprehension, for we could not haue taken hold of many small things vnlesse there had bin fastned some hard body to strengthen and establish the fleshy extremities of the Fingers, which must be also sharpe or edged to enclose a fine and slender body, that otherwise would haue slipped from betwixt them. The Toes had nayles to couer and defend their extremities, and beside in station to beare the Toes against the ground with more resistance. As for scratching or clawing, or any such other vse of the nayles, we thinke it to be of the *by* and not of the *Maine*.

The conclusion.

Thus at length haue we, through the diuine assistance, brought vnto end a long and painefull labour, worthy indeed to haue beene vndertaken by a man of more sufficiency and of greater experience in this Art then I would haue my selfe esteemed to be; my Age & Meanes not affording me time or opportunities to doe that which I haue earnestly euer affected. But for recompence of these Defects (gentle Reader) I haue pressed the footsteps of the best and most approued Authors; wherein as my first and most simple intent was the bettering of my owne knowledge in so necessary a part of my profession, so being periwaded that thy profit might fall in with the same, I haue set before thee a Mirrour, wherein thou mayst see the true representation of thine owne Originall, Structure, Growth and Accomplishment: and learne thereby to giue the glory and profit of thy Creation, to him that according to his mighty working did first poure thee forth as a few drops of Milke, and after curdled and sam-

med thee vp into so exquisit a forme as thou art become the most wonderfull of all workes of wonder. To him therefore so admired and propitious a Creator, as-

cribe with me all honor and praise, and consecrate the glorious Temple of thy

body, and the Altar of thy Soule vnto the Deity, who created them first

of nothing, redeemed them when they were worse then nought,

and hath promised eternall mansions for them, to partake

with Himselfe, of euerlasting

Felicity. *H. C.*

The Printer to the Reader.

After Michaelmas Terme in the yeare 1629. A body was brought from the place of Execution to the Physitions Colledge to be Cut vp for an Anatomy, and by Chance, the officer of the Chollidge brought the body of a cruell Wretch, who had murdered the Son of one Master Scot a Chyrurgian of goodnote in this City. This Wrech was of a very truculent countenance and aspect, as the Almighty God would therein discover the cruelty of his heart. His haire was black & curled not very long, but thick & bushy, his forehead little above an inch high, his browes great and prominent, his eyes set deepe in their socketts, his nose crooked with a round knob or button at the end which also somewhat

and deformed body.

The Preface.

He Art of Medicine which we commonly call Physicke, is con-
uersant about the health of the Body of Man; the most noble
Subiect of the whole Creation, if we except onely the Soule;
whose coniunction also with the Body, as it makes some of the
bodily operations more sublime, so it puts a greater honour
vpon that Art whereby such sublime operations are preserved
in their due tenor and integrity; or being vitiated are restored
to their pristine perfection. This Art (as all others) had her
Infancy, Childhood, Youth, and is at length growne to that
perfection of strength and accomplishment of parts, that the

Additions which are now made may seeme but a sagination to over-burthen it with vn-
necessary store; albeit we may not doubt but that some Moderne Diuine wits, may not
onely gather new consequences from the Dogmaticall Principles of the Ancients, and so
amplifie the Reuenues, but also purchase vnto our Art new Inheritance. In the Infancy of
Physicke, it fared with her as it doth with yong Children, whose indulgent Parents make
obseruation of and blesse themselves in any towardlinesse bewrayed by speech or gesture;
which may promise pregnancy in the time to come. The visible effects of the Art in hea-
ling of wounds, drawing arrowes out of the flesh, reposing luxed ioynts, setting broken
bones, and the like, were the first pledges of future proficiency, and the operations there-
fore were worthily had in great estimation. This part of Physicke was after called Chi-
rurgery, wherein, though learned men of all Ages haue taken great paines, as well in inuen-
ting instruments as remedies; yet the manuell administration they most what referred vn-
to seruants whom they trained vp for that onely purpose; Not that I suppose any worke
of Art to be dishonourable for the Artist to be employed in; but the sweetnesse of contem-
platiue knowledge, and the State and Estimation of Curing secret and abstruse diseases,
led those Sages from that which might be performed by others, to set themselves apart
and to spend their time in the disquisition of many subtilties which arose in the Physiologi-
call, Semeioticall, Pathologicall, Prognostique, and Therapeutick parts.

And hence only it is, that Chirurgery is famed for Antiquity: The euidence also of Sense
(because a Chirurgian may for the most part see his way before him, & feele how his Cure
commeth on) gaue it the priuiledge of Certainty aboue Physicke, wherein sometimes
Fortune, Nature alwayes hath an especiall claime. But neither that Antiquity, nor his Cer-
tainty doth free Chirurgery from the Alleageance she owes to Physicke; yea, they both
intend it rather: Antiquity, because it vshered Physicke into the World, but as a Hand-
maid of Honour; Certainty, as being a pledge onely and gage that Faith and affiance
might be put in that Art, in whose courser Administrations men might see and feele the
prooffe and effects.

My meaning is not hereby to Eleuate the worth of Chirurgery, but to put more honour
vpon it by assigning thereto a prime place in the Commencement, and a due respect
throughout the whole progresse of the Art of Physicke. In so much as those who are the
most expert Chirurgians, and would be so esteemed, doe strue at this day to furnish
themselves, not onely with the Physiologicall part (which they take to be of absolute ne-
cessity for their vse) but also with the Principles at least and Aphorismes of all the rest. It
cannot be denyed but that the manuell exercise is better learned by practise and experi-
ence,

ence then out of bookes: but as in Physicke there be many, so in Chyrurgery there be some speculations, which who so is incapable of (and all those are vncapable, who haue not at least some competent knowledge in the Theorie of Physicke) he shall neuer be worthy to be accounted a Master in Chirurgery. But to leaue that to be excolated by the posterity: For the present I haue been preuailed with, to this second edition of the Anatomy, to adde in fauour of yong Chirurgians, the deformation and explication of some such Instruments of this Art as may be of most vse. Wherein I will not tie my selfe to any method, because neither the peeces are perfect in their number, neither will the Volume to which the Anatomie is risen, admit of so large Addition. It shall be sufficient therefore briefly, and without any great circumstance to exhibite these formes and the vse of them out of *Pate-ns*, for I could not chuse a better Authour, that you may know the Printer will not spare for cost, to present you with the rest, if he finde these acceptable; especially if he can obtaine the body and substance of the Art of Chirurgery, to accompany these shadowes of a few Instruments and operations. Neither are you to expect curiosity in these very descriptions, but facility rather: for they are ordained for the vse of beginners. And euen for those rather, that they might vnderstand how other experienced Chirurgians goe about their worke, then that by this only manuuction, they should rashly aduenture vpon al these Administrations: but rather that they should be stirred vp to obserue the footsteps of others, who are better able to guide them; which they may do a great deale the better when they haue the Notion of these workes in their heads, before they haue their parts in the Aduenture. As also if they finde that Notion to be vnperfect, they may resort either to the counsell, or to the experience of such as can perfect it, and assoyle their doubts, which I foretell them will be many and important. Take this therefore in good part, such as it is, and that may haply perswade me to doe more for thee. Take my counsell also to exercise thy selfe rather in these and such like operations, then to bungle in the Practise of Physicke, wherein I am certaine thou hast lesse vnderstanding, if at all thou vnderstandest thy selfe.

The

The Practise of Chirurgery.

CHAP. I.

For the opening of Tumors.

When a Tumor is ripe, that is, when there is in it *Pus confectum*, at which time all symptoms of heate, paine, and the like, are mitigated, and the head of it is growne mucronated and soft, then it is time to open it, and not before. Neither ought the Chirurgian afterward to linger, for feare the humour shut vp in the flesh, should contract a venemous, or at least a malignant disposition, and by his contagion, infect the neighbouring parts. And this is especially to be feared, where the adjacent parts are of more exquisite sense, or of greater dignity: as also where they are more subiect to the confluence of excrements, or in a more prone position; for the waight of humours will naturally decline.

This apertion is made sometimes by a phlegme or lancet, sometimes by a penknife, as we call it, sometimes by Cauteries.

The phlegme or lancet, is that Instrument wherewith they vse to open a Veine, and may be of vse in tender and soft parts, and where the Apostemation is outward: The figure of it you haue here vnder set.

The forme of a Phlegme.

for with it the hand may be carried more steadily; you may strike deeper (if need be) and without danger that your Instrument should faile you. Heere you haue the figure ioyned to the handle, but turned out, to shew the crooked blade marked with [C] for that is most fit for almost all manner of incisions. Where there is any different forme to be vsed, you shall haue it expressed.

The forme of the Penknife standing out of his handle.

But because some faint-hearted Patients are afraid of this Instrument, Chirurgians haue devised to fasten the point of a Lancet or Knife in the midst of a piece of Coyne, to stand out as far as they would haue the wound to be deep. That coyne they couer with some thin Ceare-cloath, to hide the edge or point, pretending that Ceare-cloath to be the Medicine which shall make way for the matter to issue; but when they haue cunningly conueyed the Coyne vpon the Apostemation, suddenly they presse it as hard as they meane to make the Incision deeper; and

and therefore they are not without diuers of them, some larger, some smaller, some with deeper or longer points, some with shorter and shallower, according to the worke they are about. Heere you haue three figures of them: the letter A shewes the round plate, or coyne wherein the point of the Knife or Lancet is infixed.

Plates or Coyne of Siluer or other Mettall wherein the point of a Lancet is fastned.

Other clealy deuices also there be to open Apostemations; as rings wherein the point of a Lancet or Knife is concluded and fastned, at pleasure to be let out, when the Chirurgians finger is neere the Apostemations. As also hollow pipes made of Cane, Plate, or Wood, as big as a little finger, wherein are contained other smaller pipes as bigge as a Swans quill, in the end whereof is fastned the point of a Lancet, at such length as the Chirurgian thinks fit for his operation. At the end of the greater cane next his hand standeth a Vice or Spring ready bent, which Spring when the Chirurgian looseth, the smaller or wider

cane whereto the point of the phlegme is fastned, suddenly is darted out of the larger cane and striketh the Apostemation as deepe as is desired, much like these bable quills which children buy at Bartholomew Faire, out of which they can shoot a Snake to scare their fellows: and indeed these deuices are but bables, the phlegme or Penknife are more certaine Instruments, notwithstanding, because some nice people are taken with such quaint deuices, you haue them hereunder delineated and explained.

Other Instruments to open Apostemations.

Rings wherein the points of Lancets are hidden.

Certaine small Canes or Trunks wherein Lancets are fastned, called Manuela or Anterior.

a, Sheweth the greater Cane or Pype.

b, The smaller Cane or Pype contained within the greater, to the top of which the Lancet is fastned or ioyned.

c, The Lancets point appearing.

d, The Spring or Vice which shooteth out the Lancet called Manuela.

CHAP. II. Of Cauteries.

Sometimes the Patients nicity, sometimes the place, sometimes the condition of the Tumor, require that Knife and Lancet be forborne, and then Apostemations may be opened with Cauteries. They are either actuall, or potentiall. The actuall Cautery is an hot iron. And this alwayes fittest where the matter concluded is poysonous, whether it be in an Apostemation, or vpon the biting or stinging of poysonous creatures, for fire is a prompt worker, vehement also and sudden, and the Eschar will sooner loosen and fall: Beside, the vehemency of actuall fire makes a greater impression vpon the adiacent parts, and keepes the issue longer open, which is the reason that in pestilent constitutions, we vse to make issues to choose with actuall Cauteries; and because the time requires it, I will tell you where it is fittest to make them, to wit, in the right arme, a little vnder the second muscle, called *Deltois*. and againe, on the outside of the left leg, betwixt two and three inches vnder the knee. But you must remember that I giue you this counsell of vsing Cauteries in cases of poyson, then onely when the poyson is in or neere the surface, and not when it hath insinuated it selfe deepe into the body. For if the actuall Cautery reach the poyson, it will extinguish it, if it cannot reach it, it will exasperate it more; beside, the payne and terrour it carries with it, weakens and affrights the Patient.

trient much, and breakes his spirits. Notwithstanding, there is frequent vse of these actual Cauteries in the *French* disease, and they are made differing, according to the severall parts whereto they are to be applyed; all which for me to prosecute, were against my present purpose. You shall finde a little hundred of them delineated in *Ambrose Parries* xviii booke, which he wrote *De Lue Venerea*. I will content my selfe to particularise in one or two and these also described by *Pareus*. In his seventh booke and the fift chapter, is an Instrument to be vsed in the cauterizing that tumor which is called *Ranula*: (it is vnder the tongue, and corrupts the speech) This Tumor if it be any other way abated, (savouring by the burning iron) it will grow againe, and he maketh such a device for it. First, he frames a plate of iron, such as you see hollowed on the inside, and with a hole in the midst. The mouth is held wide open, and the plate applyed to the Tumor, so that the hole therein may fall iust vpon that part of the Tumor, which you would open: then with a red hot crooked iron like this in the figure, pierce the Tumor, and therewithall, with your thumb vnder the root of the Chin, beare vp the Tumour with some force and strength, that you may pierce it the deeper, &c.

The forme of the Iron plate and of the actual Caution.

In the tenth Chapter of the same Booke, hee describes the manner of the vse of the Caution in *Empyemate*, that is, when vpon a squinzie or pleurisie, or other wayes sometimes, there is a notable collection of purulent matter in the capacity of the Chest. This is a worke not to be aduentured vpon by one man, but hee had need of the best helpe hee can get; neither will the skilfullest Chirurgian vndertake it, without the aduice and presence of the learned Physitian. But it is to be performed on this manner. The Chirurgian must begin to number the ribbes, from beneath upward, till he come to the third true rib, betwixt that and the fourth must the worke bee done. Where the Chirurgian shall place (vpon the side the Physitian shall designe) an iron plate with a hole in the midst, fit for the Caution to enter into. That plate having strings at the foure corners, must bee tyed on the other side of the Patients body, so fast that it may not moue, and it must also be bowed somewhat compasse, that it may comply with the fashion of the ribbes. In the Cauterizing iron, there must be diuers holes, wherethrough you shall put a bolt of iron, at that distance from the point which you will allow to make the perforation: so if the plate bee fit, the hole of it even with the distance betweene the third and fourth rib, the Caution red hot, and the bolt in it that it pierce not too deepe: Finally the Chirurgians hand steady, and the assistants enow to hold the Patient, the worke is soone and safely performed.

And this operation is called *Paracentesis*: some of *Pareus* his counsell which followes I doe not so well like.

A type of the actual Caution, & his plate to be vsed in the opening of the side.

There is an other like operation in *The Efflu- la,* the Fistu-
lures.

la of the eye; but I leaue or referue that as more curious for skilfull Artists to thinke better vpon. Neither am I ignorant of many other actuall Cauteries made of melted lead, scalding water, roots of Gentian and the like burnt red hot; nor of that *Vstio Arabica*, mentioned by *Plinie*, approued and described by *Dioscorides*, and commended by some of the late Writers for the Hip-gout. But it were beside my purpose to insist vpon that or any other particulars. Euen potentiall Cauteries I pretermit, because I limit my selfe for the present, to describe a few Instruments onely.

Notwithstanding before I part from this place, I will take so much liberty, as to aduise the Nouice Chirurgian what he ought to represent to himselfe before he open any Aposteme, either with the knife, or with the Cautery.

1 The first thing is, that somt Apostemations are mortall, and some so dangerous that
2 they must not be medled with at all, or not without great circumspection and assistance: as
3 all Apostemes of inward and noble parts, though they appeare outward, as those in the Li-
4 uer, spleene, &c. Againe, beware of opening an Aposteme in an acute and originall Fe-
5 uer. Thirdly, take heed you mistake not Ruptures for Apostemations, either in the flanke
6 or in the cod. Fourthly, take heed of Apostemes which happen in the heads or tendons of
7 Muscles. Fifthly, beware of an Aposteme, if the basis of it appeare broad without any vi-
8 sible acuminated. Sixtly, you must open an Aposteme as neere the declining part of the
9 tumor as you can, that the matter may issue out of it of it owne accord without forcing.
Seuenthly, in incisions beware of a great branch of a veine, or more especially of an artery,
which you may many times meet withall, in the necke, armes and legges. In the eight
place, if you meet with a tumor in the legs of a dropsie body, where the dropsie is confir-
med, and the Liuer ouerthrowne, take heed of opening it, for it will neuer heale but Gan-
grenate: and you shall bring misery and death vpon your Patient, and discredit your Art.
The like may be said of an old and effoete body, in what part soeuer the Apostemation be.

Finally, (for it were tedious to pursue all) if you meet with an Apostemation which
will yeeld abundance of matter, take not all out at once, lest you take life & all, but empty it
by fits and degrees. Some of these Cautions you must also remember in making of issues;
but for the manner of doing that worke, it is so obuius that I need not insist vpon it. I
haue forgotten my selfe too much already. Onely because the *Cancer* aboue all Tumors
hath most need of the actuall Cautery, if a man may come to apply it; and because the fa-
shion of a Crab doth represent the horrid forme of that Vicer, whence also it hath his
name; you haue here a Crab figured to make vnto you (as it were) a representation of a
Cancer.

CHAP. III.

Of some Instruments to be used in the swelling and exulceration
of the Columella or Vuula.

Ecause in the former Chapter I made mention of the searing of the *Ranula*, a
Tumor vnder the tongue, I thought fit in this place to adde the figure of that
Instrument which they call *Speculum oris*, together with a *Spatula* to hold downe
the tongue, because by it the mouth is kept wide open, and the tongue couched,
when the Chirurgian would worke in it by section, constriction, or any other operation.

Speculum

Speculum Oris.

Now in the mouth next, the *Isthmus* of the throat hangs a fleshy particle, called *Columella*, we call it commonly the *Vuula*; but indeed it is then onely truly *Vuula*, when it is swelled and hangs low vpon the throat; sometimes it will be extreemely inflamed, and looke like a ripe and blue Grape of a *Cancerous* colour round and fiery. Mitigate it then you may by opening the veines vnder the tongue, &c. But *Pareus* sayes you must not vex it any way: but if it be rather swelled then inflamed, and that by a distillation from the head, then (if other ordinary courses will not abate it, but that it lies continually vpon the throat, as if it would choake a man) he may flie to the helpe of Chirurgery. And for this purpose *Honoratus Castellanus*, Physitian in Ordinary to the *French King*, deuised a fit instrument to twitch some part of it, which part will in short time fall off, and no fluxe of blood will follow it. First, he frames an iron rod, the length of a mans finger, and to the top of the rod fastens a ring about the bignesse of the end of the ring finger, the vpper circumference whereof is a little hollowed, that a thred of silke may ride in it: Then he prouides another rod, with a hole drilled in the top of it, through which the taile of the thred falleth after the riding knot, or noose is put vpon the circumference of the ring. These rods, with the noose of the thred vpon the ring, and the end issuing through the hole of the second rod, he puts into the mouth, till the ring be put vpon the *Columella* so farre as he listeth; then he drawes the noose of the thred, which easily separateth it selfe from the ring, and twitches so much of the *Columella* as it comprehends. The thred had need be strong and waxed, or I thinke it may be better done with a small line of horse haires, whose noose haply will stand open or till it be gotten about the *Vuula* without an instrument, but more easily about a *Polypus*, any Warts or excrescences in other parts: but you must remember that euery day the noose (whose end hangs out of the mouth) must be gently strained, by putting it through the hole of the second rod, and thrusting the rod vp to the noose which is about the *Columella*, till the vnprofitable part fall away. You haue three figures of this Instrument, that you may vse which you please.

The type of Constrictory Rings with threads fastned to them to twitch off a part of the *Columella*, *Polypus* or the like, if there be need.

A, the rod with the ring, whose vpper circumference is somewhat hollowed.

B, The thred or line which compasses the ring with a noose or running knot.

C, The second rod through which the thred passeth by a hole in the top of it whereby the noose is to be gently strayned.

But if beside this swelling or relaxation of the *Columella* (of which we haue already spoken) there is also an eating *Vlcer* adioyned (as sometimes it happens) and a flux of blood with it; then it will be necessary to seare the *Vlcer* with a Style blunt at the end, and red hot

hot running in a hollow pype, somewhat thicke, neere the end whereof, a little window or gutter, as it were, is cut out, so that the hot end of the Style, through that window or gutter, may arrive iust at the Vicer, without offending any part of the mouth beside. The formation of all the parts of which instrument, you haue herunder annexed.

The pipe guttered, or with a small window cut out neere the end, unto which the red-hot Style is conueyed.

CHAP. IIII.

Of the Paracentesis in the Dropsie.

Here is a great question among Physitians, whether it be according to Art, to administer the *Paracentesis* in a Dropsie. I will not stand to dispute the question, onely one obiection there is which must be satisfied. If the Liuer be not vitiated, say some, then the Dropsie may be cured by other meanes. If it be vitiated, then this operation is in vaine, because the cure is desperate, and in a desperate cure to torment and trauell the Patient so much, and beside to discredit a mans Art, is a trick of him that seeks worke for his owne ends. I answer, that there is a great Latitude in the indisposition of the Liuer in a Dropsie. If the Liuer be in fault alone, or originally, as alwayes it is not: For sometimes the Liuer is ouer-cooled indeed, and the serous matter thereupon gathered in the capacity of the *Abdomen* in great quantity, yet such a Liuer may be restored; especially if it be not perboyled too long in that Lye. Sometimes it is *schirrhous*, and circumscribed, and yet is recovered, if the water be in due time taken away. But if the worke be deferred till the whole frame and tenor of the Liuer be ouerthrowne, then indeed it is in vaine to open the *Abdomen*, because a principall part is vtterly forfeited. But if there bee any hope that the Liuer may be restored (which none but the diligent Physitian is able to discern) then the *Paracentesis* is fit to be vndertaken after this manner. If the Dropsie proceed originally from the Liuer, the section must be made in the left side, the bredth of three fingers lower then the Nauell, as neare the edge of the right muscle as you can imagine; so you shall auoyde the white line and the tendons of the rest of the muscles of the *Abdomen*. Place therefore your Patient vpon his right side, then let the Chirurgicalian pinch vp the skin with two fingers in the place before mentioned, together with the fleshy pannicle vnder it, and so pinched and held vp, hee shall diuide it ouerthwart to the very flesh, and then draw vp the skin he had hold of as hard as he can toward the Nauell, which when it falls againe, will assist him much to consolidate the wound he makes in the flesh. Then let him with great care diuide the flesh of the muscles and the *Peritoneum* with a moderate wound, and so that he offend not the Kell or the Entrals; Into that wound he shall insinuate a crooked pipe made of silver, of the bignesse of a Goose-quill, and about two Inches long, with a broad head that it slip not in; in that head make two holes for strings to runne in, whereby the Quill may be steadily tyed about the body to the wound. Into the head of the quill put a Sponge, and when you would let it runne, take out the Sponge, but the quill or pipe you must not take out, before you haue let goe as much water as is fit, for if it be once out, it will not easily be gotten in againe, without trouble and paine to the Patient. For the proportion in letting out the Dropsie water, I must referre you to the aduice of a learned Physian, who, according to the quantity of the Tumor, and the strength of the Patient, must moderate your operation. Finally, the Chirurgicalian must be carefull (beside the ties of the quill to hold that steady) to provide also fit ligatures, and strong with pledgets, &c. to contract and make firme the orifice of the wound whereinto the quill is insinuated, lest the humour get a vent by the wound and spoyle all. The figure of the quill with his head and ties, you haue hereunder expressed.

The

The fashion of the Quill or Pype to draw out Dropsie-water.

CHAP. V.
Of Ruptures.

T Here be many sorts of Ruptures, or Relaxations, whose names are taken from that which falleth downe: for it is the *Peritoneum* or Rimme of the belly onely which is broken or relaxed in them all. Sometimes the gut, sometimes the kelly, sometimes both fall together; and the Relaxation is at the productions of the *Peritoneum*. Vnlesse it be that we call *Exomphalos*, when the *Peritoneum*, at the Navel is relaxed or broken, and the guts or kelly, or wind, or flesh, or humor, make a Tumor in that place; which I haue seene as big as a mans head. I will not particularise heere of all the kindes, onely let me tell you, that in children a cure may be made according to the first intention as we say, but after childhood not so, or at least very rarely, and by accident, as it happened to the Priest *Pareus* makes mention of; then the Trusse is most in vse. Sometimes also the golden ligature.

For the Trusse, it is made diuers wayes by diuers men, some of Holland, some of Fustian, of Taffata, &c. Some stuffed with Bumbast, some are made of Steele which in my opinion are the best and the easiest, if they be made light and fit. All the skill is in fitting them to the Patients body, but first the Tumor must be genly returned vp. I know there is a trick lately brought out of *France* to trusse a man vp with I know how many Ells of Holland, and I beleue there may be some skill in the manner of the tying of the *Fascia*, but I haue experience that it hath done more harme in heating the backe and sides then good, by the fastnesse of the Ligature. Neither doe I thinke it possible to make any Ligature of that kinde so firme as the ordinary Trusses are, especially if we would vse the backe and shoulder band to our Trusses, which I see few doe. Wherefore my Counsell is, that men thus affected, resort to such Chirurgians as make their trusses themselues, and can fit them precisely. I haue exhibited two figures of them hereunder.

The figure of a man broken on one side, together with his Trusse, whose bolster hath three swelling inequalities, two in the vpper part, and one in the neather, and betwixt them somewhat hollowed, that it may not ly too hard vpon the shere bone. This will serue when the gut or the kelly falls into the groyne.

A, A *Fascia* or band that goes ouer the shoulder, and is fastned behind and before to the girdle of the Trusse to keepe it in due place.

B, The girdle or Trusse.

C, The cavity of the Boulster in the midst of the swelling inequalities where it is better stuffed.

But if a man be bursten on both sides of the Groyne, which is a thing not very vnusuall, then the Girdle is made like the former, but there must bee two Boulsters, or at least a Boulster fitted for both sides, hauing a hole through it, whereat the Yard may issue; the fashion of it is such.

A figure

A figure of a man burst on both sides; together with the fashion of a Trusse, with a double Boulster; and a hole in the midst for the Yard: the inside of the Boulsters must be like that before described.

When the excrements fill the gut which falleth downe into the Cod, and so the gut cannot bee issued backe by the rupture by which it fell, *Pareus* hath devised a refuge in that last extremity: An Instrument to cut the Cod, and so the *Peritoneum* larger then the rupture, that so the gut with the excrement may be returned vp againe. But this may be a helpe in a deplorate case, and needes a hand more curious then stands in need of my helpe to direct, and therefore I passe it by. The perforating of the *scrotum* in a water Tumor about the Cod, or in the Navell, are easie operations, I will not stand vpon them.

There is also another trick to cure a rupture, by giuing the fine powder of a Load-stone in Water-gruell, or the like inwardly, and strewing the filings of iron vpon the place tumified; but looke for this in *Pareus Lib. 7. Cap. 15.* But he tooke the manner of the Cure vpon trust.

CHAP. VI.

Of the Golden Ligature, or Golden Punch as they call it.

Here is another way of curing the Rupture, or Relaxation of the proceffe of the *Peritoneum* by incision, in which a man is alwayes castrated, because the *Spermaticke* vessell issues through the said proceffe or production, and this way beside the castration, is also very dangerous, because oftentimes great fluxes of blood follow, and sometimes the parts Gangrenate, beside, the dissection of a branch of a nerue of the sixt coniugation which is transmitted to the Testicles; ad hereto inflammations, conuulsions, and other like fearefull symptomes which follow this castration, and commonly death also. All which to preuent, the Chirurgians haue inuented a quaint way which they call the golden Punch or Ligature, because it is done with threds or wyre of gold. But *Pareus* likes better to doe it with Lead, and to other manners of Administrations prefers this which I shall now describe vnto you, because the Lead he vses, he afterward takes away, whereas the golden wyre must be left within when the wound is healed.

Lay the Patient with his thighes somewhat high, and his head somewhat low. Then diuide the skin a little about the share-bone, where the Tumor is, as farre as the proceffe of the *Peritoneum*, which with a Probe about the bignesse of a Goose quill, insinuated into the wound, and strained vpward, they carefully seuer from the fibrous and neruous particles which cleaue vnto it, as also from the *Spermaticall* vessell, and the *Cremaster* muscle of the testicle. When they haue thus separated the proceffe, they conuey vnder it a small wyre of Lead, and whip it once about the proceffe as farre as they conceiue it is too much relaxed, but leauing the *Spermaticall* vessels free. The ends of the wyre with a paire of small Pincers, or Mullets made for the purpose, they straine together and twine; neither too loosely, lest they leaue a way for the kell or gut to fall downe againe; nor too hard, lest they intercept the passage of the spirits, and of nourishment from the parts thereunder, and so they Gangrenate. The very ends of the wyre they suffer to hang out at the wound.

When

When that contraction of the *Peritoneum* is in time (put case in 12 or 15 dayes) growne callous, then they gently untwine the heads of the wyre of Lead, and loosning it by degrees draw it away, and then heale vp the wound. The figures of all the Instruments for the performance of this operation, be hereunder delineated; euen the crooked Needle with the thred in it, if the Chirurgian would work after that manner, and the Pincers to crop off the golden wyre, if he would doe it after the second manner; as also the Mullet to twine the Lead, if he will performe his worke the third way, which I haue described onely for breui-ty sake, and referre the Chirurgian to *Pareus* for the rest, in the sixteenth Chapter of his se-uenth Booke.

A, Shewes the crooked needle with a hole neere the end, through which the thred or wyre of gold is drawne.

B, The wyre or thred it selfe.

C, The Pincers to crop off the wyre.

E, the Mullet which wreathes the ends of the wyre in compasse.

There is another way to doe this worke with a Causticke, pretended to be safer and easier then the former, but I doe not conceiue it to bee so, and therefore I passe it by. One thing onely I thinke fit to adde, by way of caution, because I my selfe had a very late experience of the like case. A child had a rupture, (as was thought) and for that infirmity had a Trusse made, and wore it a yeere or more; at length vpon further disquisition, I found that there was but one Testicle in the Cod. The other was not descended, but lay in the flanke, and was mistaken for a Rupture; the Trusse being remoued, and the childe now grown to be about seuen yeeres old, the Testicles descended into the *scrotum*, and the Tumor in the flanke vanished. Such an experiment *Pareus* hath, and truely it was his experiment that led me to finde this error committed in this childe.

To particularize concerning the seuerall sorts of Ruptures and their Cures, were to entertaine you too long in an vnfit place; yet I will not forget to remember with honour that Haudy Chirurgian Master *Gillam*, who in a Patient of mine, cured a great *Hydrocele* or watery Tumor in the Cod, neuer vsing any Seton, haire, needle, or silke; but with his Lancer diuided the *scrotum*, and the pellicle wherein the water was contained, and let it out, and healed it vp againe, after which it neuer grew.

CHAP. VII.

Of five kindes of Sutures.

THe next thing I will intreat of, shall bee the manner of making sutures, or seames; wherby Chirurgians vse to sew vp wounds, when they find it necessary, & that is whe the sides of the wound cannot be fitly ioined together by a ligature or swath-band, as in most transuerse wounds it hapneth, because the flesh & other similar parts being dissected ouerthwart, flye & are contracted toward the whole parts, and so make a greater separation, whereas if the wound be lengthwise, the separation of the part is not so great, but that a fit Ligature may vnite them againe. In which operation it is generally to be obserued: First, that there be no *heterogeny* left in the wound, no peece of the weapon, or the like.

like. Next, that the suture be immediately made after the wound is giuen, or as soone as may be; and againe, that the deeper the wound is into the flesh, the more flesh be also taken vp with the needle, otherwise if the surface onely be sewed, the flesh vnderneath the suture which is wounded, will turne into quittance, and apostemate into a caue or hollow Vicer.

There are five kinds of sutures.

The first vsed in fleshy parts, not fit to be swathed, is after this manner.

The needle must be long and slender, and toward the point three-square, like a Glouers needle, for so it will pierce better; the eye somewhat hollowed that the thred may bee hidden, as it were, in the gutter of it, and so it will more easily follow the needle. You must also prepare a siluer quill, with a window cut out toward the end, whose whole side you shall place against the lip of the wound which you meane to pierce with the needle, as well to keepe it steady and firme against the force of the needle, as also that by that window, you may perceiue when the needle hath pierced so much of the skinne and flesh as you desire, and through it may also draw the needle and his thred without shaking or moving the sides or lips of the wound. When the wound is stitched vp, tye a knot vpon the thred, as neere the skin as you can, and cut off the rest that it sticke not to your Emplaisters.

But in the stitching you must obserue, that if the wound be any thing large, you must take the first stitch about the middest of the wound, and the second in the midway between the first stitch and the end of the wound, and the third answerable to the second, for betwixt euery stitch there should be aboue halfe an inch distance. Neither must you draw the lips of the wound close together with your stitches, but leaue a distance betwixt, that out of that distance the quittance may vent it selfe as it groweth, for otherwise it will not onely cause paine and inflammation, but so tumifie, that either the stitch or the thred, or both, will breake. Obserue also that in taking vp the skinne with the needle, you take not vp too much flesh with it, for that will increase the paine and inflammation, and make the Cicatrice or scarre more deformed. But haue due regard to the depth of the wound, and the shallower it is take vp lesse flesh, the deeper more. Yea, sometimes the wound in fleshy and brawny parts will be so deepe, that it will be necessary to provide a crooked needle, and a crooked quill or Canule, to performe the worke, and therefore you haue hereunder described of both sorts as well straight as crooked, for seuerall vses.

A type of the Quills and Needles required for the making of a Seame or Suture.

Obserue by the way that the silke thred waxed, is to be preferred before the thred of Line: and *Blondus* giues a good reason for it, for it will not so soone rot as the other.

The second kinde of Seame or Suture, is like that of Glouers, or that

of the Skinners in sewing their Skinnes together. And it is vsed when the entrals are wounded, lest the excrement should issue out. I doe not beny but that it is possible such a cure may be wrought, but how hard it is to come to them, to doe the worke, and how dangerous after it is done no man doubteth; yet any thing almost may be attempted to saue life, if it may be, and Nature sometimes doth incourage vs to that which Art would thinke and leaue as desperate.

The third kinde of Seame, is that which Chirurgians vse in the Cure of the Flax-lip, that is, when the vpper lip in the middest, is separated the one halfe from the other, and that from the birth, as it hapneth many times. They vse the same Suture also when the lip is so wounded by accident, as also in maine deepe wounds of the flesh, whose lips are farre distant. The needles (for they must be diuers, sometimes many) must be triangular or foure-square, almost throughout the length, and the thred well waxed that it breake not. That needle (if one stitch wil serue) must be thrust through both sides of the wound or breach, and take vp all the flesh of both lips, and there sticke halfe the needle at one lip of the wound, or breach

breach, and halfe at the other; and in the same manner, another short needle (as the place will beare) must be thrust in the middest, crosse the former, and vnder the flesh as the former is. Then the thred which was in the eye of the first and longest needle, must be strayed crosse about all the foure ends of the two needles, seuen or eight times, or more, to hold the lips of the wound or breach firmly together till the vnion be perfected, and then the needles must be taken away, and the wounds they make healed according to Art. But if it be a Hare-lip that was a fault of Conformation, the skin on both sides of the diuision must first be cut away, otherwise the sides will not vnite. The figure of this kinde of Seame you haue hereunder expressed.

The forme of the Suture for the Clouen or Hare-lip, together with the needle and thred rowled about them.

The fourth kind of Suture is called by a proper name *Gastrographia*: and is proper to the lower Belly, when the muscles of the *Abdomen*, and the *Peritoneum*, are mainly wounded; in so much that some of the entrals sometimes fall out, but the *Omentum* alwayes, at least a part of it. If the wound passe no further then to the *Peritoneum*, it may be cured after the ordinary way of curing simple wounds: but if the *Peritoneum* be wounded, then the worke must be performed after this manner. First with your needle take vp the *Peritoneum* alone, for example, on the right side of the wound, (for you may begin on which you please) and passing by the left side of the *Peritoneum* take vp the flesh of the muscle, & the skin with it on the left side. Then take vp the left side of the *Peritoneum*, and passing by his right side, take vp the right side of the muscle and skinne. Then take vp the right side of the *Peritoneum*, and passing by his left side, take vp the left

side of the flesh and the skinne, and so sew your Seame crosse in and out, till the whole wound be seamed. The reason of this manner of seame is, because the *Peritoneum*, being a membranous part, and without blood, cannot re-vnite, vlesse it haue a bloody part ioyned to it, which in this manner of suture it hath quite through the length of the wound. You must also obserue, that this seame must be sewed as close as well may be throughout the length, till you come to the decliue or lower part of the wound, there you must leaue a stitch at least, both in the membrane and in the muscle, at which vent the *sanies* and matter may issue, till there be none left, and then it must be healed vp with a *Cicatrice*. Obserue also, that if any of the *omentum* issue out of the wound, it must not be reposed, but cut off; for that fat is feculent, and if it once take the aire, or rather the aire take it, it will putrefie. Also if any of the entrals issue at the wound, the Patient must be laid in such a position as they may best be reposed, and that must be done with great tenderneffe and easinesse of hand, that the ayre come as little to them as may be, and that they be not violated or shuffled in the reposition.

The fift kinde is called the dry Seame, which is vsed onely in wounds of the face, to auoyd scarres which will make the face deformed. For that is the market place, especially in women, to please whom Chirurgians haue deuised this kinde of Suture.

According to the bignesse of the wound, you must cut out a paire of Indentures, of strong Cloath, in the forme hereunder described. These you shall spread with the following Medicine, or steepe them in it. *Recipe puluerum Mastich; sanguinis draconis, thuris, farine volatilis, Tragacantha contuse, gypsi, picis, sarcocolla, ana dra. 1. picis nigra scruples 2. grain 5. albamina onorum quæ sufficient, fiat medicamentum.* These cloathes you shall lay vpon the face, at the opposite lips of the wound, so that they may be distant the breadth of a finger, and so suffer them to lie till they cleaue strongly to the skinne of the face. Then with a needle and thred, straine the indented opposite corners together so hard, that the flesh (to which they will firmly cleaue) may be drawne together with them, and so be revnited by such meanes as you shall finde to be fit. But be carefull with fit bands and tyes about the head to establish your worke, that it stirre not till you haue brought it to perfection. The fashion of the Indentures and their application is hereunder expressed.

The Figure of the dry Seame.

withall, hold the eye steady, that with a paire of small Pincers you may pull out that which offends, which sometimes will be fast fixed, or adhere close to the membranes. This Instrument must be so artificially made that according to the bignesse or smalnesse of the eye, or as you would haue it extended or drawne in, it may be made wider or narrower, at your pleasure. This is the forme of it.

and the very Naturall humour of the Eye issueth out. To auoyd this mischiefe, wee are constrained to vse the helpe of the *Seton*, which is often found to be a remedy (not in this disease onely, but in many others) and many examples I could bring of it, if I did not purposely command my selfe to be short as I may, I come therefore to describe the vse of the *Seton*.

Place the Patient vpon a foot-stoole, and bow his head downe-ward, to stretch the skin of his necke as much as you can. Then with your fingers separate the skin, together with the fleshy pannicle vnder it, from the muscles of the necke; then set on the tongues, so that the holes perforated in them, may stand vp and downe, not ouerthwart the necke. Pinch him hard, that the paine of the tongues or pincers may take away the sence of that which followes. Haue your probe ready three or fouresquare at the point, and immediately as bigge as a Goose or Swannes quill, crooked at the end, and red hot; that probe you shall enter into one hole of the pincers, and issue at the other; hold it in no longer then it hath made a good Eschar, then draw it out, and put in a needle made large for the purpose,

with

CHAP. VIII.

Of some offences of the Eyes.

WE spake last of the wounds of the face in the end of the last Chapter, wherefore here I will also prosecute some accidents which happen about the face also, and ad- solue what I haue to say, concerning it, yet so that I will meddle onely with such accidents as require the vse of the Instruments I haue to describe, to which in this small addita- ment I tie my selfe.

First therefore many small motes fall into the Eye which are some- times hard to get out, and being sharpe, or otherwise of euill quali- tie, breed an extreame and insuffera- ble offence. If by turning the eye- lid ouer the end of a *spatula*, you can- not finde that which offends, then you may vse the Instrument hereun- der described. You must insinuate it vnder the eye-lids next to the white of the eye, and so separate the liddes as farre asunder as you can without too much violence, and

Againe, the Eyes are often vexed with sharp and most impo- tunate Defluxi- ons, so that some- times the Horny coat of the Eye is broken therwith,

with a thicke fourefold thred of Cotton-wooll, or rather Sleauē filke somewhat twisted, and wet with the white of an Egge, and a little Iuice or infusion of Roses mingled together. After that, couer the wound with double cloathes, wet in the same liquor, and binde it vp. The next day annoint the necke with Oyle of Roses, and for a few dayes renew the double cloathes, moyfined as before; but the *Seton* or string which is in the wound, must be gently drawne to and againe, and rubbed ouer with this following Medicine.

Recipe Terebinth. Veneta ounces 2. syr. ros. & de absynthyo. ana drams 2. pulueris Treos, diacridij, Agarici trochiscati & Rheiba anagr. xv: incorporentur omnia simul & fiat medicamentum. And this must be vsed as long as you would keepe the wound open.

The Figures of the Pincers, Probe, and Needle, are hereunder expresse d.

CHAP. IX.

Of some offences about the Nose, and the Eares.

THe Nose as it is the chiefe beauty of the Face, if it be whole and proportionable; so if it be violated or deformed, it disfigures the face most, and therefore the Poet calls the wounds of the Nose, *inhonesta vulnera*. As if they did dishonest a man. Yet because the Nose stands out vpon the Face, and hath it selfe no defence, it is subiect to more outward iniuries then the rest of the parts about it. The vpper part of it especially, because it is bony, is subiect to bee broken, which when it happens, it may be thus amended. First, you shall frame or whittle a sticke somewhat broad at the end, like a little *Spatula*, and whip it about with Towe, or with a Clout, which you shall put into the nostrils, and therewith restore the bones to their right places and figure. Then with stupes or cloathes moyfined with an *Adstringent* Medicine of Masticke, bole *Armonia*, *sanguis draconis*, and burnt Alumē, made vp with the whites of Egges, you shall couer the sides of the Nose, for that will establisth them, and then binde it vp with a fit Ligature, not too hard, least you make the Nose crooked and saddled, which beside the inconueniences it brings with it, will be a great disfiguring to the Face. After you shall prouide two small pypes, or tunnels, not exactly round, but somewhat depressed with holes in the end, and about the end, by which the *Sanies* may issue, and also the breath may be drawne in and returned. At the outward end, let them bee a little more compasse, and a small ring fastned to them to tie a string vnto, which string you shall so fasten about the night-Cap, that the Tunnels may be held within the nostrils. These will containe the bones of the Nose in their due position, till the cure be perfected. The figure of them you haue hereunder expressed.

But if a part of the Nose be cut, and there be any quantity of flesh remaining, whereby the wounded part may receiue life and nourishment, it will be good to sew it vp, otherwise the wound cannot be restored, vnlesse it be by that quaint deuice of taking a new nose out of the skin of the Arme, with the description of which operation, I will not trouble my selfe nor you at this time; or a new nose counterfeited, as *Pareus* teaches.

For the eares if the Cartilages be cut away, there

there is no hope of recovering them; but if the Cartilage be so cut, that some part of it hang by the skin, it may be sewed vp againe, yet beware you pierce not the Cartilage with your needle, for then it will gangrenate, but onely the skin, and as much of the flesh as you can take hold of, which compasses the Cartilage. The rest of the Cure must bee accomplished with Stupes, and deligations and such Medicines as may prevent inflammation and other accidents. But beside, beware that you defend well the hole of the Eare with a Sponge, least any thing get into it; for sometimes by such neglect, some small portion of flesh will grow into it, whereby the hearing will be depraued, if not viterly on that side lost.

CHAP. X.

Of the Convulsion of the mouth.

BEfore I goe from the Face, I must admonish you that the causes of Convulsions, being often about the head, which is the originall of the sinewes, and the temporall muscle being neare vpon the Lesion, whereof Convulsions doe often ensue, it is worth your care to know how to prevent the Convulsions of the mouth. For the Teeth will sometimes in such a case be so closed, that it hath beene knowne that the end of the tongue hath beene quite bitten off. To prevent which mischiefe, as also that the mouth may be kept open to receiue medicines fit for the cure of such a disease, the Chirurgians haue inuented an Instrument, which they call *Speculum oris*, whereby they can open the mouth, and part the Teeth wider and wider at their pleasure. But you must remember that when you perceiue any beginning of a Convulsion of the iawes, yea, when you haue reason to feare it will follow, if your Instrument be not at hand, put a sticke, a spatula, or some such thing betweene the Teeth, to hold them so farre asunder, that the tongue may not be violated, and that there may bee a way open to enter in the *Speculum*, which it will be hard to doe, if the Teeth be quite set, as we say. Heere you haue two of those Instruments delineated, the one close, the other dilated.

CHAP. XI.

Of the five sorts of Fractures of the head, and of the signes of a Fracture in generall.

HAuing done with the Face, we come to the Head, or rather to the Scull, which is subject to so many sorts of Fractures and Contusions, that it will take vs vp sometime to distinguish the into their kinds: which yet I will do as briefly as I can, & much more briefly, then a businesse of so great consequence should be handled, if I did not tye my selfe within so narrow cencels as I haue before prefixed. There be therefore five kinde of Fractures of the Scull. The first is called *Fissura*, a Fissure, or Cleauing, such as in an ear-

then pot or glasse when they are crackt, and the cracke runnes along in it. The second is called *Contusio* or *Collisio*, a bruise of the Scull, wherein there may be also a smal depression, but the bruise goeth on farther then the vpper shell or table of the Scull: for the Scull consisteth throughout of two Tables or Shells, betwixt which there is so much distance that one may be depressed especially in children, & in womens heads) though the lower be not offended. The third fracture is called *Effractura* when the Table or Tables are both depressed and shattered into pieces. The fourth is called *Sedes* the Seate. This name *Hippocrates* gaue it, because the weapon wherewith the blow was giuen, makes as it were a seate for it selfe in the Scull, and leaues his impression therein. The fift and last kinde of Fracture is called *Contra-fissura*, or the Counter-fissure, because the cracke is in the opposite part, to that which received the blow. All these kinde of Fractures haue some things common: especially the

the second, and the third, because they haue also many obseruations and Instruments particular and proper to these seuerall kindes, I thinke fit to handle them particularly, yet with my accustomed breuity. But before I come to the particulars, it shall not be amisse in generall to giue you the signes whereby you may know that there is a Fracture made. And these signes are of two sorts: some are such as doe perswade our reason, some conuince our sense. The signes that may reasonably perswade vs that there is a Fracture made, are these. If a man fall from high vpon a hard place, or if a hard and heauy body fall from high vpon his head. If vpon the blow he presently fall, but much more if the lye for a time deprived of speech, sight, and hearing; if the paine (after he comes to himselfe) be vehement and doe perseuere, so that he is constrained often to moue his head to the part affected: if when he awakes out of the astonishment he fell into vpon the blow, his minde or reason be not perfect but disturbed, his sight dimmed, and his head remaine giddy, as it is in the *vertigo*; if blood vpon the blow issue out at his eyes, nose, eares, or mouth, or finally if he vomit shortly after the stroke. The reasons why all these be signes of a Fracture, I must not here unfold, you must take my word for the present. You may also gesse shrewdly at a Fracture by the forme of the weapon, by the force wherewith the blow was giuen, if it were seene; if it were not seene, by the wrath or fury, or strength of him that gaue it, if his head were bare and without defence when the stroke came, and if it were downeright and not sidelong.

All these and many other the like circumstances may leade a man that is vigilant, and hath as we say, his eyes in his head, to iudge whether there be a Fracture committed or not. For although some of these accidents may happen without a Fracture, yet if many of them come together, especially of those I named last, they will put the case out of doubt.

Paulus Aegineta hath another way to know whether the Scull be crackt or no; where the wound is, he remoueth the scalpe and the *Pericanium* from the bone, and knocks it with an iron Probe, and if from that knocking there result a dull sound, such as a crackt Pitcher yeelds, then he takes it for granted that there is a Fissure; but surely to distinguish such a sound by such a meanes, I take to be very difficult. *Guido* conceit sounds better, and beside limits the very place of the Fracture, yea, the extent of it, if it proue true. Let the Patient hold one end of a small cord hard betwixt his foreteeth, and the Chirurgian the other end in his hand, and straine the cord hard, and then moue it as you would doe the string of an Instrument, and in the very stroke, saith he, the Patient shall be admonished, where the Fracture or Fissure is, and the paine will make him point directly to the place. *Pareus* hath no faith to beleue this experiment, as hauing tryed it often and neuer found any certainty in it. Thus much for the signes which may perswade our reason; there be others which will conuince our sense, which we may see with our eyes, or feele with our hands, or with our Instruments which cannot deceiue vs. Among these is reckoned that of *Hippocrates* his obseruation, if the haire stand vpright and stiffe in the wound, if the Chirurgian can with his finger feele a roughnesse and inequality any thing sharpe in the wound vnder his finger, or a manifest depression of the Scull. If yet a man cannot iudge of the Fracture, he must make a decussate incision in the Scalpe, that is to say, he must cut it crosse, so as the incisions may meet in the midst of the place suspected, and lay the bone bare, and then if he cannot see the Fracture with his eyes, he must grope after it with his Instrument. This Instrument must neither be too slender nor too sharp, least if it happen to stick in any naturall inequalities of the Scull, it might deceiue vs; neither must it be thicke and blunt, least it might passe by and not offend at a small Fracture. If when this Instrument or Probe arrives at the bare bone, there be nothing to be felt but smooth and slippery equality, then there is no Fracture; but if the Probe meet with any roughnesse, especially not in the way of the Suture, then there is certainly a Fracture. Yet must the Chirurgian remember that sometimes it may happen that there is a Fracture euen in the place of the Suture, and then it is hard to be discerned, vnlesse it be a very great Fracture, because the roughnesse of the Suture hides it, in which case *Hippocrates* himselfe confessees hee was deceiued. And beside, in some bodies the sutures are more close, in some more open, in some more equall and smooth, in some more vnequall and prominent. All these things the ocular Chirurgian must waygh in his minde, and with them compare the reasonable signes before mentioned, and so doing, it is not likely he can be deceiued. Thus much of the differences and signes of Fractures in fauour of yong Arts-men, though it be beside my intention. Now I proceed to the particular sorts of Fractures.

CHAP. XII.

Of Fissures of the Scull, the first kinde of Fracture.

He first sort of Fracture of the Scull, is the Fissure, which when the Chirurgian shall know to be committed, and yet the wound in the Scalpe is not large enough for him that he may dexterously apply himselfe to the cure of that Fissure, then he shall first shave off the haire as wide as he shall thinke fit, and with a Lancet or Incision knife, diuide the skinne and *Pericranium* from the bone, in a three or foure cornered incision, that is, thus T, or thus X, and to that magnitude which he shall destine to himselfe; but yet he must be carefull as neere as he can to auoyd the place of the futures, and especially the Temples. Neither let him make any scruple thus to make way for his worke, for it is a lesse detriment to wound the skinne (though it proue there bee no great need of it) which hee may easily heale vp againe, then to be ignorant of the nature, kinde, and extent of a Fracture, for want of seeing his way before him. This Incision he may make with a Lancet or Penknife, as we call it, or an incision Knife, the figures whereof, though you haue expressed before in the first Chapter, yet I haue thought fit here againe to discipher.

But whereas I told you that you must make your incision in the Scalpe cornered, you may provide that the wound which was made with the blow, may fall in as it may to make vp the corners of your incision. Alwayes provide that your knife be sharpe, and your hand so heauy, that together with the hairy Scalpe, you diuide also the *Pericranium*, and presently separate it cleane from the bone; for if it remaine vpon the bone, and come afterward to be torne by the Trepan, being of exquisite sense, and so neere of kinne to the *Dura mater*, that it is thought to be a production thereof, it will induce vehement Feuers and other Symptomes. Wherefore beginning at the inner corners where your incisions met, raise it vp with such an Instrument as is hereunder delineated.

When the *Pericranium* is well separated, fill the whole wound with pledgers of fine Lint, to keepe the lips

farther asunder, and aboue it apply remedies to stay the fluxe of blood, which if it cannot be stayed with medicines, and that you can find some notable branch of a veine by which it issueth, enter a needle with a thred on the outside of the Scalpe, and returne it againe from the inside outward, so that the thred may crosse the vessel, & then with the two ends of the thred w^{ch} are now on the outside of the scalp, tye a knot as straight as you think fit, to twitch vp the veine, which you would stanch: but betwixt the thred and the Scalpe, you must enterpose a rowle or pledget of Lint for a boulder on both sides, that the straining of the knot may neither cut the flesh, nor offend the skin, and breed more paine then is necessary; when you haue so stanchd the blood, leaue the head boulderd vp. And such a stitch is sometimes of absolute necessity, as when an Artery is wounded, for then no restrictive or binding poulders or medicines would doe the feat. And we finde in daily experience, that in outward parts, as well as in inward, we shall light vpon an Artery of some largenesse, where we did not dreame of it; so various is Nature many times in the diuersifying of the vessels. At the next dressing (which would be next day) the Ligature need not be loosed, and

and yet it will be time for the Chirurgian to resolve himselfe whether there be a Fracture or no, and of what kind it is. If he cannot find the Fracture let him wet the bare bone with writing Inke, adding thereto a moment of Oyle of Roses, and if there be any chinke or cleft in the bone, the Inke will pierce into it. The next dressing he shall carefully cleare the Inke from the bone with Lint, and then with an Instrument which they call *Scalprum* or *Radula*, made of Steele, with a head like a *Compasse Chesill*, or like a broad Arrow head, or like a hooked Chesill returned somewhat at the edge, he shall scrape or scale the bone, and if he finde that which he scrapes off to be blacke, it is a signe that there the Fissure is, because the Inke hath dyed the bone, and then he shall continue scraping till the dust come white, without any tincture of the Inke, for then he may presume he is past the Fissure. Sometimes the Fissure will guide him to continue scraping or scaling, till hee come to the very membrane or meninx: but if he would know before whether the Fissure be in both the Tables of the Scull, he shall try it thus. Let the Patient stop his nostrils and his mouth, that no breath issue out, and then let him strive to expire with all the power he hath; and if both the Tables be clouen, the Chirurgian shall perceiue a bloody *Sanies* to issue at the cleft, for the ayre so pent will make the meninx to swell, and a frothy moisture will sweat out. In such case the Scull must be scraped or scaled to the very meninx, yet great care taken that that be not touched. But if the Fissure be long, it shall not be alwayes necessary to follow the whole length of the Fissure with your scraper, for Nature will restore it of her selfe, if there be way enough made for the *Sanies* to issue, whereby symptoms are auoyded, and the corruption also of the bone. Within three dayes this worke would bee performed; yet if it happen that the Chirurgian be called later, he shall doe well indeed to tell the standers by of the danger (for most perish who are long neglected) but yet he shall apply himselfe to his worke, as if he had beene sooner called, because God and Nature doe often assist a diligent hand beyond expectation. But obserue that in Winter there is lesse danger of delay then in Summer, because the parts are in Summer more subiect to inflammation then they are in Winter. You haue hereunder diuers of these Instruments expressed of seuerall fashions, together with the handle by it selfe (for one handle will serue them all) whereinto the Instruments for more steadinesse must be scrued.

These two Instruments will serue for the scaling of greater bones. Thus much of a simple Fissure.

CHAP. XIII.

Of Contusions of the Scull, the second kind of Fracture.

A Contusion, which is the second sort of Fracture of the Scull, sometimes hapneth with a breaking of the skin, sometimes without. It happens without, when the Instrument wherewith the violence is offered, is obtuse & equall; Yet neuerthelesse there happens an *Ecchymosis* vpon it, that is, an effusion of blood gathered vnder the Scalpe, in the place of the

Contusion. If that effusion of blood be small, it may by fit medicines be discussed, but if it be great, so that the Scalpe rise from the Scull, it must be vented and purged by incision. Neither after must you vse suppurating Medicines, as in a fleshy part you should doe, because all moist things are enemies to the bones. This Contusion hapneth very often to children;

children, who cannot hold their feet; and beside, if they be metled, they are very busie, and get falls, and the Scalpe of their heads being soft, collects much such like serous and clodded blood. After the Incision and euacuation of this serous blood made by gentle Compression, you shall finish the Cure (if there be no Fracture) with drying medicines. But if vpon a great Contusion the Scull be depressed like the print of a bruse in a Brasse or Pewter-pot, so that you may feele the dint with your finger, you may expect a little (if the dint be not great) whether it will rise againe of it selfe, as it will do in the moist heads of children, women, and such as are phlegmaticke; but if it doe not rise, you shall set on a Cupping-glasse with much flame, and command the Patient that he stop his Nose and mouth, and then force his breath vpward; for by these meanes the depression may rise; if not, you must make Incision to the bone, and fasten vpon it a Wimble or Piercer with a screw, and therewith draw the bone vpward, till it be in his owne place, as Coopers vse to raise their Vessels when they are sunke too much downeward. But if the bone be so thicke or strong that the Wimble will not retract it, then you must perforate the Scull in the center of the depression, and vse the Leuer hereunder deciphered.

A, Shewes the point or tongue of the *Leuator*, which must be obtuse or blunt, that where it is insinuated as farre vnder the Fracture as the *meninx*, it may not offend it.

B, The body or steale of the *Leuator* which must be foursquare that the tongue fastned in it may be steady. The end of this steale must rest vpon the sound bone, that it may rest the firmer. The vse of it is, That when the point or tongue is vnder the depressed bone, lifting the Haft or Handle vpward, the bone depressed may be heaued vp.

C, Shewes the first arme of another *Leuator*, whose hooked end is by degrees insinuated vnder the depressed bone.

D, The second arme of this *Leuator*, which must rest vpon the sound bone, to assist the first in heauing vp the depression: but in the vse of this second *Leuator*, you must depresse the haft or handle, for so his first arme raises vp the depressed bone, whereas the handle of the first *Leuator* must be lifted vpward as farre as is need to raise vp the bone depressed.

But if it happen that the bone be fractured and depressed on one side onely, that thou maist raise that side and also make way to vent the *Sanies* or *ichorous* matter thereunder contained, thou mayest vse small Sawes, such as are here described, to diuide the Scull, and cut off without compression, so much of the bone as shall be needfull without danger of pressing downe the broken part of the bone vpon the *meninx*, frō whence much mischief might arise.

But if by such signes as haue been before related, or by any other, you shal be conuincied in your iudgment, that the Contusion is onely in the vpper Table of the Scull: You shal safely

ly take out that depressed part with a small Trepan, whose handle is like the handle of a Ioyners Piercer, but the Bit most like the Instrument whereby those that make Button-moulds doe turne them out of the wood. The handle and the Bit are here both expressed.

CHAP. XIII.

Of an Effracture of the Scull, the third kind of Fracture.

The third kinde of Fracture is called *Effractura*, that is, when vpon a vehement blow the Scull is not

dinted onely, but sinks, and the Table or Tables are broken asunder, for so much the word signifies, and sometimes into many peeces; seven peeces of the Scull I saw taken out of a Childs head in the *Old-Lurie*, which the wheele of a Cart pressed against a wall, yet hee recovered. And because in this kinde of Fracture, the bones being separated and loose, may be taken out without trepaning, Chirurgians haue prepared small *Leuators*, whose formes need not be expressed they are so common; they be crooked, turned vp widely at each end contrary wayes, and a little broader at the end, as it were spooned, which spoone also is rugged and vnequall, to fasten better vnder the splinter which you would raise vp and loosen from the membrane; but on the embowed side they must be very smooth, for that side touches the membrane in the operation, and leanes a little vpon it.

But there must be great care had, least in taking away these shreds or splinters, we offend not the membrane, which oftentime is compressed, sometimes wounded by them: sometimes it happens that these splinters runne vnder the Fracture so farre, as they cannot be gotten out vnlesse it be enlarged. In such a case, if there be space enough to get one of these paire of tongues or pincers vnder the bone, you may snap off so much of it as will discover the splinter, and make way for the drawing it out, better a great deale, and with more ease and security to the Patient then you can vse the Tripan or Trepan. Beside, the businesse hath not so much circumstance, but may be suddenly done. Now wee know that to do a worke suddenly and securely, is of great commendation. The fashion of these tongues or pincers, or both, are herevnder described very accurately:

And because in these Fractures, not onely for the remouing and raising of Splinters, but also for the smoothing and making the edges of broken bones, and plaining them, there is vse of diuers sorts of Chisels, Pincers and the like; as also of a Mallet, you haue many fashions of them here described, that you may take your choyce, as you shall finde occasion to require.

For

For it must be considered, that as much as is possible, the Chirurgian ought to auoyd, not onely the hazzard, but even the offence of his Patient, and if he can take vp and separate the broken bones with a simple *Leuator*, let him neither vse the Pincers nor the Tripan. If the Pincers will serue let him not vse the Tripan, for it hath been obserued, that in vsing the Tripan sometimes, where there hath been no necessary vse of it, so much of the Scull which was but split, hath been loosned, as hath induced terrible consequences, which might haply haue been auoyded, if that hard

course had not been taken; for as I haue said before, Nature many times takes vpon her selfe and perfects such cures, as if an Artist should meddle with, he would spoyle all: For it is not for nothing that God hath prepared that *Meditullium*, a bloody and alimentary substance betweene the Tables of the Scull, but that by it as by marrow baked into a callous substance, the diuisions of these bones might be vnited. Wherefore my counsell is that the Chyrurgian should bee aboue all things carefull that there be way made for the euacuation of the *Sanies* or corrupt matter in euery Fissure and Fracture, but otherwise, that he striue not too much to bare the meninx, nor in deed more then he must of necessity doe, prouided that he leaue no inequality or asperity of the bone to grate it.

CHAP. XV.

Of the Seate, the fourth kinde of Fracture.

The fourth kind of Fracture is that, in which the weapon so sits in the Scull, that the Scull carries the print of it, neither longer nor shorter, and therefore *Hippocrates* (a happy Author, not onely of things, but of names also) calls it *Edo. Sede* the seat, for as a Hare settles in her Forme, so the weapon settles in the Scull, and leaues his impression in it, *ad amussim*. The seates are of diuers kinde, some superficially, some are impressed to the *medetullium*, some depresse both the Tables, some are long, some short, some broad, some narrow, according to the forme of the weapon, and the force which was added to it. The Instruments whereby this kinde of Fracture is releued, are the same we haue spoken of before, and those onely; excepting the Trepan of which wee shall intreat by and by. In the meane time it is to be noted and diligently marked; That if it happen that a part of the Scull be absolutely broken or cut from the rest, yet if it hang to the *Pericranium* and the Scalpe, it must not be pulled from them and throwne away as vnprofitable, but may be reposed againe in his owne place and Nature will vnite it to the bone of the Scull, by the interposition of a *Callus*, as she vnites the skinned by a *Cicatrice*. This *Celsus* obserues, and *Pareus* tells a Tale of a *Capsaine*, a great part of whose fore-head-bone, was so sliced with a sword, that it hung onely by the *Pericranium* and the musculous skin of the forehead, and fell vpon his eyes, that the meninx might be seene bare. He clenched away the blood from the meninx, and returned the bone into his place, and established it in the vpper part, with a seame of three stiches to the scalpe, and filled vp the rest of the sides of the wound with pledgets of Lint, that there might bee way left for the *sanies* to vent it selfe, and the bone that was cut fastned it selfe to the rest of the Scull, and the man recovered.

CHAP. XVI.

Of the counter, Fissure which is the fift kinde of Fracture.

Inally it hapneth sometimes that there is a Fissure in the opposite, or contrary part of the Scull, to that which receiueth the blow; so that if the blow were vpon the right side, the left is clouen, & on the contrary. This kind of Fissure is by so much the more dangerous, by how much it is harder to finde. *Paulus Aegineta* laughs at *Hippocrates* for making mention of it, and his reason is, because, though an empty glasse or pot, may be after that manner counterclouen, yet the hard and full Scull cannot

cannot as he conceits. But *Pareus* auoucheth that he hath seene it, and calls it *Resonitus* and *Contrafissura*: but withall saith, that it hapneth when the futures of the scull are obliterated, and the Scull growne to be all one bone, or at least when the futures are very close. Moreouer, he is of opinion, that *Hippocrates* meant also that the same bone of the Scull may receiue the stroke in one part, and be fractured in the opposite part; although the futures be naturall, and as they ought to be: but you must conceiue that the part opposite to the blow in the same bone, may be vnderstood two wayes. First, when the fracture is in the same superficies of the bone whereupon the blow did light, as if the blow did alight vpon that part of the *bregma*, which is next the *Lambda* future, and the fissure happen in the part of the same *bregma* which is next the *Coronall* future. Secondly, when the vpper superficies or Table of a Bone receiued the blow, and the nether table of the same bone, is cloven, of which kinde *Pareus* tels a story of a Knight who belonged to the troope of Horse, vnder Duke *Stephanus*. His discourse you may see in the eighth chapter of the ninth booke. The cure of this kinde of Fracture *Hippocrates* himselfe, who first wrote of it, pretermitted, because he could not conceiue how it should be discovered, and therefore for the most part it proued mortall. But *Pareus* would not haue it so neglected, but where by coniecturall and the rationall signes before described, it may well be suspected, he would haue the haire of the head shaued close, and a plaister put on made of Tarre, Pitch, Waxe, Turpentine, *iris* and Mastich duly mingled. If vpon the vse of this plaister any part of the skinn become moist, soft and tumified, vnder that he imagineth the Fissure is, especially if the Patient vn-awares, as it were, and without manifest sense of paine doe lay his hand vpon that part. In such a case, and where some of the signes of a Fracture before mentioned doe second his conceit, he calls in the helpe of a learned Physitian, and then fore-telling the danger that the Patient is in, he sets a Trepan vpon the Scull. For there are foure conditions of a Fracture, wherein the Chirurgian may easily be deceived, and thinke there is none, when indeed there is a Fracture. The first, when the Scull is lightly depressed, and shortly riseth againe into the due figure. The second, when the fissure is small and hairy, like the rift in a glasse which yet will hold water. The third, when the lower Table is fractured, the vpper remaining sound, at least to the sight. And lastly in this fift kind of fracture, which we call a counter-fissure or *Resonitus*.

CHAP. XVII.
Of the Trypan or Trepan.

HAue often before made mention of the Trepan, an Instrument by which a peece of the Scull depressed, or otherwise fractured, may be turned out. There are foure things which perswade a Chyrurgian to vse the Trepan. The first to raise vp a depressed bone, when the Piercer before spoken of will not serue the turne, and beside to take out the fragments of broken bones, who doe presse or lye hard vpon the membrane, or the substance of the Braine. The second, to make way that the blood and ichorous matter, which vpon the breaking of a vessell, floweth vpon the meninx, may be washed, dried vp, or otherwise vacuated and consumed, which would corrupt not the membrane onely, but the braine it selfe. The third, that the way may be made more open and plaine, for the application of such remedies as are fit to expedite and make the cure more facile and easie. Lastly, and especially this Trepaning supplies the defect of bands and swathes to inhibit the fluxe of blood, which cannot be vsed in fractures of the Scull for many reasons; first, the Sphericall figure of the head will not hold a swathe, vnlesse it be too straight and fast: beside, the thicknesse and hardnesse of the Scull will not suffer the Vessels to be straightned with any swathe or band, so that a notable flux should be stayed or inhibited: as for the vessels of the Scalpe which are without the Scull, the compressing of them with any Ligature would breed vehement paine and inflammation. For such a compression would intercept the pulsation of the Arteries, and keepe in the effluxion of these footy excrements, which vsually exhale by the futures. Moreouer, it would constrain the blood from without inward vpon the membranes, and consequently vpon the braine it selfe, whence the feauer, extreame paine, convulsions, apostemations of the Braine, the palsie, the apoplexy, and death it selfe would soone follow. These be the causes why the Trepan is more necessary in the fractures of the Scull, then in the fractures of other Bones of the Body.

But

But before the Trepan is set on, you must set the Patient, especially his head, in a fit posture, and prop it vp with swathes and pillowes, that when you come to your worke, it cannot sinke; as also that as little outward ayre as is possible may attaine vnto the wound, or the membrane in the trepaning; for there is nothing more enemy to the Braine then cold. Now we know that the warmest ayre in the hottest Summer day is farre colder then the membranes or the Braine, and therefore expert Chirurgians, when they goe about such a worke as this, beside the muniments before spoken of which they place about the skull; they also provide Chafindishes of coales neere hand, that no cold ayre pierce at the wound or trepaned part. Obserue also that the eares of the Patient must bee well stopped with Lint or Bumbast, as well that no blood nor any of the medicines which are vsed, doe get into the eares, as also that the hole of hearing being so cloyed he may not heare the noyse of the Trepan or other instruments which haply might affright him. Finally before the Trepan be set on, it will be fit to drill a hole in the Scull, with a three-square Wimble, in the place where the center of the Trepan must be fixed; and therefore the point of that Wimble must be no bigger then the point of the center of the Trepan is: Such a Wimble you haue hereunder demonstrated.

A, Shewes the handle of the Wimble.

B, The Bit whose head is serued into the handle and pointed three-square.

The Trepan it selfe is a round Saw, with a center or point in the midst, which being fixed in the bone, the circumference is mooued,

and cutteth out a peece of the bone as bigge as the circumference is. They are made of diuers magnitudes for the diuers vses there may be of them. They are framed of many peeces. A Steale or Handle, much like that of a Ioyners Piercer to be turned round. The round Saw it selfe with a hollow shanke, wherein the center or three-square point is contained; a round case for the Saw, which standeth a little off from it, and hath no teeth in it, for it is made to guide, limit and proportion the descent of the Saw into the Scull, that it touch not the membrane. There is also a Vice set vpon the shanke of the Saw, neere the head of the Handle, with a small shanke in the side of it, whereinto they put a scrue Pinne, to hold the shanke of the Case wherein the Saw runnes firme and stable that it moue not. All these particular parts and peeces of the Trepan are seuerally and particularly delineated in the figure following; and beside you haue also a pourtraiture of the whole Trepan with all the parts ioyned together, that in one peece you may see how to ioyne all into one Instrument, and how to take the parts asunder.

A, In the Figure to the left hand, sheweth the whole Trepan, with all the parts ioyned together.

B, the head of the handle in which the Saw is fastned.

CCC, the shanke of the Saw.

D, the Saw taken from his Case.

E, the Vice.

F, the screw which fastneth and firmeth the Saw to the Handle.

G, another screw which fastneth the Vice to the shanke of the Saw.

H, the Center or Point of the Trepan.

A, In the figure to the right hand, sheweth the whole handle of the Trepan.

B, the Case of the Saw.

C, the Vice.

DD, the Screwes which firme the Vice of the Saw.

E, the Saw without his center or point.

F, the Saw furnished with his Center or point.

There

There is another sort of Trepan or Trefine, now generally in vse amongst our *London* Chirurgians, called the hand Trepan, the head of it is made Taper fashion, smaller at the teeth, and greater vpward, with cutting edges round about on the outside, to make way for it selfe; the shanke of the head entreth into the sockets of a straight stemme, and is made fast into it with a screw: the handle is made crosse the top of the stemme, like the handle of a Gimblet (but longer) and both ends made in the forme of an *Elevatorie*, and serue (the perforation being made in the Scull) to eleuate the depressed bones. This with a semicircular motion of the hand, performeth the operation with great security, for the perforation being made it cannot slip in to endanger the hurting of the *dura mater*, as the other may doe: they that will may vse this head, with the handle turning round like a Piercer before described.

Now you know the forme and fashion of the Trepan, I will acquaint you also how you shall vse it.

When you haue bared the bone, washed the head, drilled a way for the center, fastned your Trepan therein, and screwed the Case to that depth, which you would haue your Saw to cut, then with a Wimble and steady hand, winde about the handle, till you haue cut away the first table of the Scull to the *Meditullium*, and entered the teeth of the Saw in the second, but entered them onely. Then take out the Center or point, and set on the Saw againe without it, for feare it should touch or perforate the meninx; for that were dangerous if not mortall. But the center being gone, you may safely turne out the second table even to the membrane, for the case, if it be duely fastned, will keepe the saw from entering deeper then to the membrane. You shall also annoint both the Saw & the Case with Oyle, that they may runne more glib and glad, and cut more sweetly. For so you see Carpenters vse to annoint their Sawes with some fresh-grease. Moreouer, *Pareus* would haue you dip your Saw and the case in cold water, whilst you are in the worke of terebration, because they will grow hot in the circumaçion, but I conceiue this will doe more harme by interrupting the operation, then it will doe good, vnlesse the worke were to continue some long time, and the circumaçion were extreame quicke, neither of which are to be feared in this businesse. The next of his obseruations is of more consequence, and that is about the scaling of the bone. For where either the Trepan toucheth, or the ayre taketh the bone, it will surely scale, and this scaling may be accelerated by sprinkling a like poulder of Rocket, Brionie, wilde Cucumer, and *Aristolochia*: but the Chirurgian must not pull off the scale, but suffer it to fall of it owne accord. When the bone is scaled, to regenerate hard and

Recipe pul. Ireos illyrica, Aloes, manna, thuris, mirrha, Aristolochia, ana dr. i. misce. When the flesh is growne, sprinkle on a poulder made of the pills of Pomegranates and Alume, burnt together, that will procure a Cicatrice and heale it vp.

The danger of the Sawes going too deepe in the Scull, makes me againe counsell you to beware that it leane not too much on either side, for the Scull is not equally thicke, and beside, being round and compasse, it is harder to guide it aright then if it were plaine, where the Chirurgian shall be carefull to know by Anatomy, where the bone is thicker, where thinner; and beside, where there is any suspition, he may measure the depth of the Sawes cut, with a small Probe on euery side, that he offend not against the membrane on one side, before the bone be sawne through on the other; but about all let him be sure the case of his Saw be well established by the Vice in due place.

When the Saw on euery side attaines to the *Meditullium*, if he would take out but one table, and to the membrane, if he would terebrate both, and yet the bone will not come out easily, you shall vse this Wimble serewed in the end, and fasten it in the hole which was made by the Center of the Trepan, and so extract it with this in stead of a Leuator.

He shal also make plaine the edges of the Scull, from whence the peece was turned, especially of the lower table, lest in the incision of the braine, the membrane should be goaded with any asperitie or roughnesse. *Pareus* hath framed an Instrument for this purpose, me thinkes with a little too much circumstance, for I thinke a paire of Pincers will doe it as well. But you shall finde his Instrument in the 18 chapter of his ninth booke. If the asperity be any thing thicke, he flies to the Chisell and Mallet but he would haue it of Leade. As for the small fragments and splinters of bones, if any fall vpon the membrane or sticke in it, they may be taken out with a paire of small Pincers.

But if that part of the Scull which is fractured will not safely admit the incision of the Scalpe to make bare the Bone as farre as need doth require, as when the fracture is vnder or neere the temporall muscle or vpon the future, then in stead of one large Trepan, you may set two or three small ones, if it be needfull, not vpon the fractured part but neere it, and so that the gutter of the second may ioyne with the gutter of the first, and the third. But if the fracture happen vpon the future, set two trepans vpon the sides, on each side one, otherwise you shall teare the sinewy fibres, membranes, veines, and arteries, by which the meninx is tyed vp to the Scull, and yeeldeth his productions for the forming of the *Peritoneum*. Againe, if you should thinke that one trepan, or one of the futures would be sufficient, you would be deceiued, because the *sanies* which vpon the fracture falleth on both sides of the future vpon the meninx, cannot haue vent, or be exhausted, because the fibres of the *dura meninx*, which rise through the future to forme the *Pericranium*, are as it were a partition wall, or hedge to stay it from issuing from that side of the future that is not trepaned, to that side which is trepaned.

To conclude, if for any reason you be willing to forbear the Trepan, you may vse another instrument, called the cutting Compasses, but the bone must be laid as bare as it should be for the Trepan. These Compasses you may separate more or lesse as you please with a Screw that goes betwixt their shankes; and the point of them, which is made to cut, you may also alter at your pleasure, hauing diuers of them in a readinesse, which you may fasten to that shanke with a Screw.

A paire of cutting Compasses to turne a bone out of the Scull.

- A, Sheweth the cutting shanke of the Compasses, which as it is wound about cutteth the Scull. CC, Two points, either of which at the knee you may fasten to the shank with a Screw, as they be fittest for your vse.
- B, The Screw which fastneth the cutting point of the Compasses to the shanke, which you may call the knee. D, A great screw which holds the Brace of the Compasses to the other shank of the compasses, which makes the Compasses wider or narrower at your pleasure. And

And because in this worke one of the shankes of the Compasse must stand firme in a certaine place whilst the other winde about to cut out the bone, it shall be fit to provide a plate of iron punched with many small holes, but not perforated, in which holes the standing shanke of the Compasses may rest without any wauering; and you must also make the plate a little curued, and hollow, that it may comply with the roundnesse of the Scull. The fashion of the plate is hereunder expressed.

You may also make your cutting Compasses with a head as ordinary Compasses are made, and the Screw whereby they are made wider and narrower, may be made round and long, to reach betweene the shankes, neere the head of the compasse. And this fashion I like better then the former, for the screw is surer, and therefore I haue caused it to bee hereunder described.

CHAP. XVIII.

Of the places of the Scull which will not beare the Trepan, of the temporall muscle, and off fungous flesh.

BEfore we part from the vse of the Trepan, it shal not be amisse to exhibite in one chapter (though we haue touched vpon some of them before) all the places of the Scull, which will not admit of the vse of the Trepan. First therefore, if the fractured bone be altogether, or for the most part, bee by the violence of the

blow, separated from the scull; you shall not vse the Trepan, either to heaue it out, or to finish the separation, for feare the waight of the Instrument, or the heauineffe of his hand that guides it, should depresse it vpon the membrane. Secondly, you shall not set the trepan vpon a future fractured for the causes mentioned in the former chapter. Thirdly, you shall not set the Trepan vpon the forehead bone aboue, betweene the eye-browes and neere about them. For first the flesh will not regenerate in that place, because vnder that part of the vpper Table there is a cavity, full of a white and slimy humour, and ayre, which reacheth on either side to the five bones of the Nose: Or say that the bone is there so thicke, fast, and solid, that no nourishing luyce can sweat through it to engender flesh. Adde hereto, that if the bone be there trepaned, there will flow vnto the place a confluence of those excrements which are vsually euacuated by the eyes and the nostrils, and those excrements will hinder the drying, and consequently the healing of the Vicer. And that the passage out of the nose and the braine, is very open to that part of the forehead, *Parvus* confirms by an experiment of his owne, in a Patient whom he trepaned in that very part, for saith he, when he shut his mouth and his nostrils, and yet did strongly expire, the ayre that issued at the trepaned place, would blow out a good great Candle. And in this place the bone in some bodies is much depressed naturally, in all bodies somewhat; so that the Chirurgian may mistake it for a depression vpon a fracture, if that part happen to be wounded, or sore brused, ylesse he haue this obseruation in his minde.

Fourthly, you shall not set the Trepan neere the lowest edges of the scull, least if there be a way open, the soft substance of the braine, pressed with his owne waight, should sinke downeward to the orifice.

Fifthly, you must not set a Trepan vpon the bones of the *sinciput* in a child, for those bones of the scull continue longest soft, and will not beare the impression.

Lastly, not vpon the Temple-bones, because of the temporall muscle, whose section or incision, saith *Hippocrates*, breeds a convulsion in the opposite temple, for being cut ouerthwart, it quite looses his proper action (to wit) of moouing the lower iaw to the vpper. And this small muscle is sometimes so tendonous and strong, that I haue known a man who could share in sunder a fixepenny naile. Now the opposite temporall muscle being found, and vsing his strength, when the wounder muscle, which is his Antagonist, cannot moue against it, it must needs come to passe, that the iaw on the wounded side, should follow the traction of the sound muscle, and so all the parts of the face must be writhen, tortured, and conuelled toward the sound side, the wounded muscle being resolved. For it is *Hippocrates* his rule, that when there are muscles (as he calleth them) *Congeneres*, in opposite parts, which are of equall number, magnitude, and strength, the resolution of one part brings the convulsion of the other.

Neither doth this mischiefe onely follow the wounding of the temporall muscle, but moueouer, because it is in continuall motiō in our speaking & chewing, being once diuided it cannot reynite. Adde hereto that the seate of this muscle is iust vnder the commisure of the stony bones; now vpon a commissure or suture you haue been already taught you must not set a Trepan. Finally, through the body of this muscle, many veines, arteries, and more sinues are sprinkled, which if they be cut, many dire symptomes must needs follow, a feauer, inflammations, vn sufferable paines, convulsions, not onely of the temple, but of the whole body, and in the end death it selfe.

Let no Chirurgian therefore be so rough as to attempt the section of this muscle, the pricking or brusing whereof with the corner of a thin trencher, I haue knowne bring death in lesse then foure and twenty houres. But if there bee need of trepaning, let him set it aboue it, or at the side of it, as neere the affected place as he safely may, not touching the muscle it selfe. *Parvus* in such a case, made his incision three cornered a little aboue the fracture, and the next day, which was the third after the wound receiued, hee set on his Trepan; within a few dayes after he tooke out foure shiuers of bones, & put into the wound a smooth pipe of Lead, with two holes in the end; euery dressing commanding the Patient to stop his mouth, and his nostrils, and to expire with all his strength, holding his head downeward, so by that pipe much matter came away, which was collected betwixt the Scull and the meninx. The other superfluties he washed away with a sponge filled with a detergent decoction, and at length cured the Patient through Gods assistance. The figures of these two Instruments are in the next page deciphered.

The pipe of Lead smooth and broad in the end, by which the Sanies was gotten out.
The spring wherewith the wound was washed.

Another story he tells, which I will insert, because of the cure of proude and fungous flesh. A mans Temple-bone was fractured with the sliuer of a stone, he fell vpon the ground, and blood issued out of his mouth, nose, and eares, he vomited exceedingly, and lay mute and astonished foureteene dayes, he was full also of convulsions, and his face was puffed vp. He was trepaned in the fore-head-bone, at the side of the temporall muscle, The five and twentieth day, a soft spungy flesh of exquisite sence, grew out of the hole made by the Trepan, whose growth no Cathetericall poulders could prohibit, yet at length he recovered. We call this fungous flesh, because it is soft and like a Mushrome, is narrow at the root, and growes broad at the top, and doth increase or diminish according to the affluence of the matter, or the industry of the Chirurgian, in intercepting it: it smells abominably, they call it in *France* Saint *Fiacers* figge. As in the barke of a tree, from the excrement of the aliment, a humour halfe rotten, thicke and glutinous, sweats through, and gathering together by degrees, is heaped vp into a Mushrome, so out of the broken vessels of the *dura mater*, and the scalpe issues blood of a melancholly temper and consistence, and is increased by that which Nature sendeth to repaire the flesh where it is decayed, and so it growes into a spungy protuberation, which therefore *Galen* saith, carries the condition of the place to which it growes: This spungy flesh is eaten away by medicines, which have a specificall quality to consume such superfluous flesh, such as are those which do dry exceedingly, but weare and eate away more moderately, such as that is which followes.

Recipe sabina drams 2. ocræ dram. 1. puluerizentur simul, aspergatur caro excrescens, or Recipe Hermodactylorum combustorum, 3 ℥. fiat puluis in eundē vsus. But if that spungy flesh (as often it happens) grow to be as bigge as an egge, then tie it as neere the root as you can with a thred of silke, and twitch the knot, till it fall off, and vpon the root strew the poulders before named, for so it will sooner die then by sharper Cathereticall medicines.

CHAP. XIX.

Of the Corruption and rotnesse of the bones of the Scull.

Sometimes corruption ouertakes the wounds of the head, and a *Sphacelus* the bones of the Scull fractured, which hapneth, because they are touched with the outward ayre, which they neuer before felt; or because the *Sanies* being concluded vnder them, putrifies it selfe, and rotnes them; or because the Chirurgian for want of skill, applies suppurating and oily medicines vnseasonably, whereby the bones lose their naturall temper, and become ouer-moyst, contrary to their nature, and the neighbouring flesh is overheated and turned into quitture, which falling downe to the bone where it findeth stay, makes the vlcer foule and sordid, and by degrees fastens vpon the bone, a malignity whereby it suffers inflammation; yea, *Galen* hath it, that the beginnings of inflammation in the Scull proceed from the bone oftentimes. This mutation to a state against nature and corruption, which we call *Caries*, may be discerned by the eye, (to wit) when the bone turnes from white to be yellowish, or begins to grow blacke: partly also by the probe, which findes it rough, vnequall, not smooth as it was wont to be, and beside, when the rotnesse hath preuailed, the probe will finde it fungous and spungy, and sinke somewhat into it, or at least beare it before it, if it be a little pressed. Yet this last signe is not perpetuall, especially after a while; for the rotten humidity in time wil be dried vp, and then the bone wil grow so dry, that a Trepan wil hardly pierce it, and yet be carious too, but the greatest argument of a carious bone is when the flesh about it is too soft, and washy, and almost without sence: This *Caries* or rotnesse of the bone must be cured with *Cauteries*, either actuall, or potentiall, such a poulder sprinkled vpon the bone is auayleable.

R. Iræos, Flor. Aristol. ana dra. 1. Centaurij drās 2. Corticis pini 3 ℥. fiat puluis subtilissimus. But if the caries be much, you shal vse the scraping instruments before described in the 17 chap. And if it goe through the whole bone you shall not diuide the corrupted part from the

found, but suffer it to fall away of it selfe; yet may you be now and then moving it with your probe, for so Nature will sooner shoot it off, but I can limit you no time. As for the place of the Scull where the Trepan ranne, the bone that hath taken the ayre, that which was Cauterized, or whereon the Cephalicall poulders have been shed, they all commonly scale with forty or fifty dayes more or lesse, according to the difference of the age, temperament and habit of the Patient: and in the like proceffe of time a broken bone will vnite by a Callus, (which as I said) was to a bone, as a scarre or a Cicatrice is to the skiane.

Sometimes it happeneth that a part of the bone is tainted with a Caries or rottenesse, but the whole bone with a *sphacelus*, and falls away. And in such a case a Periwig may be artificially made to defend the head from outward iniuries, for the bone cannot be restored, neither can any plate of gold be so couched that the scalpe should grow ouer it, and he that tels not his Patient so, is an imposter, and will conuey the gold into his owne pocket.

CHAP. XX.

Of the mischiefs that happen to the dura meninx in the Fractures of the Scull.

IN the Fracture of the Scull, most what the fault of the Chirurgian in vsing the Trepan, and other Instrument, sometimes is the cause that the *dura mater*, or *meninx*, i. the membrane next vnder the Scull is violated by being cut or torne. The medicines to cure this fault are called *agglutinantia*, as if we should say, gluing, or sawdering medicines. *Paras* hath a good one which is this. *Recipe Colopho. dram. 3. myrrha, aloes, masti. dis. sanguinis draconis. ana dram. 1. croci ℞. sarcocolla dram. 8. misceantur & fiat puluis subtilis.* The other part of the cure which is to cleanse the wound from *Sanies* or any other rotten matter, gotten betwixt the Scull and the meninx, may be performed by a probe with lint, or rather a ragge rowled many folds about it, and wet with syrrop of Roses or wormewood, and a little *Aqua vita*; and this the Chirurgian shall doe every dressing, commanding his Patient to stop his nose and mouth, and then expire as fast as you can, that so the matter to be euacuated may rise, and the probe to meete with it. Moreover, because the meninx, if it be tumified vpon incision or laceration, will rise and haply be offended against the rough edges of the Scull which was cut with the Trepan or otherwise vnequally fractured, therefore you shall prouide for your probe, a round and smooth and broad head, wherewith you may gently depresse the membrane, that so the sanies may haue free vent: and this you shall also doe every dressing and then sprinkle on your sawdering powder, and after lay a sponge vpon it, moystned with a drying and corroborating decoction, and after well wrung. The decoction may be such as followeth out of *Paras*. *Recipe fol. salvia, maiorana, betonica, rosarum rubr: absynthij, myrtilorum, florum chamemeli, meliloti, stoechados utriusque ana m. 3. ℞. radicum Cyperi, Calami aromatici, ireos, Caryophyllatae, angelicae, ana 3. ℞. bulliant omnia secundum artem cum aqua fabrorum, & vino rubro fiat decoctio;* Or instead of this decoction you may moysten the sponge with Malmesey and a little *Aqua vita*. Above all put a plaister of *Diacalciteos*, but made liquid with vinegar or Wine, wherein Roses haue beene steeped. Remember alwayes that you passe no straight Ligature vpon the Scull, nor any thing which is heauy, or hard, for those things will breed paine and inflammation: and let the Patient, if he can, lie vpon the wounded side, and now and then hold his Nose and mouth close, and expire or breathe out as strongly as hee can, (as I haue before said) for so the sanies will better issue. Notwithstanding, let the Patient in the position of his head, finde his owne ease most what, for Nature it is who must perfect the Cure, and therefore molest her not too much.

Sometime vpon the vse of the Trepan, or otherwise the meninx may be inflamed and swell with a phlegmoue out at the fracture about the edges of the Scull, vpon which inflammation many grievous symptomes must needs ensue. Heere I would not haue a Chirurgian, though expert, goe alone but call for the aide of a Physitian: but the worke of the Chirurgian shall be to enlarge the orifice with his cutting Pincers, described in the foureteenth chapter; the Physitian may consult about bleeding, purging, dyet and the rest. In the meane time the inflammation may be mitigated with such a fomentation. *Recipe sem. Lini, Altheae, feniculi, psil. ros. rubr. ana 3. 1. solani, plantaginis ana M. 1. bulliant in aqua Cornuani & fiat fons.* You shall also instill into the eares *Anodine* and repellent medicines, or what else the learned Physitian shall prescribe. But if all this proceffe will not serue the vaine, but that there remaine a suspicion that there is some purulent matter concluded vnder

der the membrane, the Chirurgian with his Lancet shall diuide it, carrying the point thereof vpward, and outward, least he touch the *Pia mater*, or the Braine it selfe. For though this be a dangerous operation, yet many haue beene knowne to recouer with it, and in extreame dangers, extreame meanes are to be aduentured vpon, because without that helpe, death must of necessity follow.

Another accident may also happen, no lesse fearefull then the former, vpon a fracture. When either through the vehemency of the blow, or the coagulation of blood vpon the membrane, or because it hath taken the cold ayre too much, or through default of the Chirurgians medicines, not proper for the part, or finally because the proper substance of the membrane conceiues putrifaction, it may happen, I say, that the very meninx will become blacke. Here the Chirurgian had need haue his wits about him. If therefore the blacknesse proceed from the vehemency of the contusion, he shall powre vpon it a little oyle of the yolkes of egges, with a moment of *Aqua vite*, a chiue or two of Saffron, and a small quantity of the poulder of *Iris*, mingled with them. And then foment it with a fomentation made of discucient and aromaticall simples, boyled in water and wine, and aboue that *Vigo's Cerate*. But if the blacknesse proceed from congealed blood, bathe it with the following decoction, till the blacknesse vanish. *Recipe Aqua vite* ζ 2. *granorum tinctorum in tenuem puluerem tritorum dram.* 2. *B. croci* $\mathfrak{D}$ 1. *mellis rosati* ζ 1. *B. sarcocolla dram.* 3. *leuiter & simul bulliant omnia*. If it come from the coldnesse of the ayre that hath taken it, vse the medicine following till the membrane recouer his colour. *Recipe terebinth. Ven.* ζ 3. *mellis rosati* ζ 2. *vitellum oui vnum farine hordie dram.* 3. *Croci* $\mathfrak{D}$ 1. *sarcocolla dram.* 2. *Aqua vite dram.* 3. *incorporentur simul & bulliant paululum*. If it proceed from the inordinate vse of moyst and oylie medicines clense it away with dryers. If from the vse of biting and hot medicines, contemper it with such as are more gentle and coole. Finally, if it proceed from the putrifaction of the proper substance, *Vigo* vseth this medicine following. *Recipe Aqua vite* ζ 2. *mellis rosati* ζ 3. *B. misce*. And if that be too gentle, *Pareus* vseth the following decoction. *Recipe Aqua vite* ζ 2. *mellis rosati* ζ 2. *pulueris mercurialis dram.* 2. *unica ebullitione bulliant*. Or this, *Recipe Aqua vite* ζ 1. *B. syr. absynthij & mellis rosati ana dram.* 2. *unguenti Egyptiaci dram.* 2. *B. sarcocolla, myrrha, aloes ana dra.* 1. *vini albi odoriferi* ζ 1. *bulliant leuiter omnia simul, colentur ad vsum dictum*. But if the putrifaction be so stubburne and refractary, that it will not yeeld to these remedies, then vse *Egyptiacum* alone, but made with Plantane water in stead of vinegar, or you may vse the poulder of Mercury alone, or mingled with the poulder of Allum. For such medicines must not be balked in such a disease. And *Galen* saith, that if there be no phlegmoue, the *dura meninx* will well endure them. And two reasons may be rendred for it. First, because hard and dry bodies, such as are membranes, are not easily affected, but those things that haue a vehement operation; secondly, because it must be the Physitians chiefe care to conferue and restore the natue temper of euery part, with such medicines as are of temper alike vnto it. But if these medicines will not preuaile, but that the membrane swell aboue the Scull, and remaine black and dry, and the Patients eies become flaming, prominent, and wandring with iactations and a phrenzie, and that these mischiefes are not momentany, but stable and permanent, then hold thy hand and say, death is at the doore.

Thus haue I runne through the diuersities of Fractures of the Scull; the Instruments the Chirurgian shall vse in them, and many of the symptomes which accompany them; wherein I haue beene more prolix, because it is a noble plate and of great and frequent vse; yet I haue passed by many particulars, which out of expert Chirurgians and Physitians might haue beene added to excellent purpose. But you must remember that considering my first intention, this that hath beene said is a worke of supererogation.

CHAP. XXI.

Of wounds of the necke and throat, and of stanching of blood.

IN the wounds of the necke and throat, I will be but brieue; those of the necke, if they be but shallow, are easily cured, if they be somewhat deeper, they are more dangerous, because there are the tendons of many small muscles; but if they pierce the *rac* bones, and diuide the marrow of the backe, then all the parts vnder the wound will be paralyticall. If the wound be in the throat, it is a venture but the ingular veines, or the sleepey arteries, or both, may be diuided, and then the fluxe of blood must be carefully stayed,

stayed, for blood is the treasure of Nature. If the artery be wounded, the blood is thinner, and comes away leaping with a kinde of subsultation. If the veine, it is thicker and blacker, and comes away more slowly. If the wound be not deep, nor any notable vessell diuided, you may clap on a pledget with such a medicine. *Recipe Terra sigillat: boli armeni, ana dram. 2. thuris, mastiches, myrrha, aloes, ana dram. 1. farina volatilis molend 3 B. fiat pulvis qui albumine oui excipiat.* And then binde it vp. *Blondus* commends this, wherewith he saith, he hath stayed the blood of veines and arteries. *Recipe vitrioli Rom. sanguinis draconis, boli armeni, pilorum leporis, aruginis lebetis, aloes, thuris, tela Arachnes, & omnia commisce cum albugine oui.* If that will not doe the feat, take away all that couers from off the wound, and with your thumbe presse the wound and orifice of the vessell which is decayed, till the blood be clodded, and so much dried about it, that it will close vp the vent. If that will not serue, you must find out that orifice of the vessell which is next his originall, and with some part of the flesh, stitch it vp, and this way also will serue the turne when the ioynt is dismembred. But because when such a notable veine or artery is diuided, the orifices will be retracted, and shrinke vpward and downeward, the Chirurgian in that case shall diuide the skin till he finde the orifice, and then stitch it vp, and afterward binde it safe, and not remoue his Ligature till the flesh be growne to couer the orifice. If the condition and nature of the part will not admit of this operation, then he shall clap on a cautery, sometime actuall when the part will beare it, sometimes potentiall, as the poulder of *Vitriol* burnt, or a little quantity of Mercury, and burnt Alume in poulder, and the *Eschar* he shall not hasten away, but suffer Nature to shed it, and so there will be no danger. It may also happen, that if the vessell be not quite diuided by the wound, the Chirurgian shall be constrained to diuide it, that the ends thereof parting asunder, the flesh of the neighbour parts may stop the flux, being assisted by such helpes as are before spoken of. But this is the last refuge, and the Chirurgian shall not ascend vnto it, if he can otherwise chuse.

If the rough artery or the gullet be diuided, the expert Chirurgian shall artificially stitch vp the wound, and in the meane time nourish his Patient with brothes or gellies, but not suffer him to eate any thing which may extend the part in the swallowing: He shall also cause his Patient to vse such a gargle warme, which will supple the part, ease paine, giue him liberty of breathing, and beside, serueth to deterge, and agglutinate, or sawder the wound. *Recipe Hordei m. 1. florum rosarum pug. 1. passul. mundat. inubarum ana 3 B. glycyrr. 3 1. bulliant omnia simul, addendo, mellis rosat. & Iulep. rosat. ana 3 2. fiat Gargarisma.* One instance in *Paraus*, I will adde, because it happened to our owne Countreyman.

Two *Englishmen* for their pleasure walked to a wood, one of them was full of money, and beside had about him a gold chaine of good waight; his Companion suddenly set vpon him, stabbed him through the weazon and the gullet, and cast him aside among certaine Vines, rifled him and leauing him for dead, got into the City. The wounded man with much a doe, got into a Cottage neere hand, where hauing some small helpe to relecue his wounds, he was brought into the City, and committed to *Pareus* his care. Hee found the weazon quire cut a sunder, which he presently sewed; the gullet which was also diuided, he could not come to stitch, for it was fallen downe vpon the stomacke: that was his death, yet he liued to bewray the murderer, who also had his deserued punishment, being broken vpon the Wheele.

CHAP. XXII.

Of the wounds of the Chest.

Wounds of the Chest which are penetrant (for of those only I will speake) are distinguished by this, because if the Patient stop his nose & his mouth, the wind will breake forth at the wound, so as it will blow out a Candle set neere it. In this case it is controuerted whether the wound should be as suddenly healed vp as may be, or whether it should be kept open. If it be kept open, the danger is, that the cold ayre will enter and ouercoole the heart, and beside that the vitall spirits will finde way by the wound, and be expended. On the contrary if the wound bee closed, the blood which falleth vpon the wound into the capacity of the Chest, cannot get out, but there will putrifie, whence will proceed Feuers, the Fistula, and such like accidents. In so much as sometimes the Chyrurgian is constrained to enlarge the orifice of the wound for the better auoyding thereof. This question is easily asfoyled. For if there be

be no blood, or very little shed into that capacity, it is best to heale it vp as soone as you can. But if there be much, you must keepe it open till it bee gotten out. But how shall that be done? You must place your Patient vpon a bed, with his head and brest hanging ouer the side, with a footstoole to leane his Elbow on, to stay his body with; and then let him stop his Nose and his Mouth that his Longues may swell, and therewith the midriffe will rise, and so the blood will issue at the wound, especially if you cleere the orifice from clodded blood with your finger, or some fit Instrument. After some part is come away, lay him at ease vpon his bed, and deliuer at the wound with a large syring an injection, made of a decoction of Barley, *Mel Rosarum*, and browne Sugar; and hauing that in his body, let him wallow on both sides, as it were, to rinse his chest, and then lay him ouer his bed side, as before, to auoyd that which was cast in, with which the remainder of the blood will also issue. The next day iterate the injection, but make it more detergent, yet put in no very bitter things, for the bitterneffe will easily passe through the Longues into the mouth, and breed an intollerable distaste. Hasten your cleansing of the Chest as much as you can, that you may leaue Tenting of the wound, for it will soone grow Fistulous. And when in the beginning, you are constrained to tent it, take heed you make not your tents of Lint, least it be drawn by the brest into the Chest, but make it of fine old Cloath, and let a good part of it hang by, or be fastned to the boulder, that you may retract it at your pleasure; for if it fall in, it is certain death: yet I know *Fabritius* in his Century, makes mention of one who caught vp two Tents which got into the capacite of the Chest, about three monethes after they fell in. Now if the wound doe degenerate into a Fistula, which it will sometimes, doe the Chirurgian what he can, then is the mischiese doubled, for Fistulaes of the Chest are scarce euer cured, and that for many reasons. First, because the muscles of the Chest are in continuall motion; secondly, because the ribs hath no other inward couering but the *pleura*, which hath little blood in it. Thirdly, because the wound hath no flesh to rest against, so that the lips of it cannot be stitched or drawne together by a Ligature, that so it might heale.

But to returne to the Syring: You must carefully obserue how much of the injection you cast in, and looke you haue it all againe returned, for if any of it stay behinde, it will do mischief. After the injection is returned, you must provide a siluer or a leaden pipe, with two or three holes in the end of it, which you may put into the wound, if it be fistulous, that by those holes the *sanies* may issue; you shall make the outward end of it broad, and tye it fast with strings, that it get not into the capacity. The broad orifice of it you shall close with a soft Sponge and large, moystened with Wine and *Aqua vite*, and that warmed together: this Sponge will not onely keepe out the cold ayre, but will also receiue the sanious matter which issueth from the wound, and so much the rather if the Patient stay his breath often, as we haue before said, and tumble on each side, especially on that which is wounded. Neither must you forbear the vse of this pipe till the Fistula become dry, then may you

safely indeuour the Cicatrice, not before. The figures of such a Syring, with such pipes and Sponge as I before spake of, are here represented, sauing that the Cutter hath made too many holes in them.

Vpon the wounds of other particular parts I will not insist, because I intend not any general Treatise of Chirurgie, but onely of the vse of some of the Instruments, and therefore I will now proceed to those wounds which come of Gunshot, about which many instruments are of necessary vse.

CHAP.

CHAP. XXIII.

Concerning wounds made with Gunshot.

IT is a grand and maine disadvantage in all professions, to take precepts and practises vpon trust, without examination of the reasons, of how great authority soeuer the Author be. I will instance in this one operation of Chirurgery, concerning the cure of wounds made by Gunshot. *Vigo* a learned man, and one who hath deserued aboue many others, excellently of the Art of Chirurgery, who also flourished in the times that were neere to the inuention of that diuellish Engine, in the eight chapter of his first booke *De vulneribus*, wrote, that wounds made with Gunshot were poysoned with the Gunpowder, and therefore prescribes that they should be cured with the Oyle of *Sambucus*, which is an extreame hot medicine, yea, a very Causticke as he vsed it, for he commanded it should be mingled with a little *Theriac*, and powred scalding hot into the wound. This authority of *Vigos*, all Chirurgians followed in their practise. So did *Pareus* himselfe, then but a yong man, Anno 1536. when he attended the French Army, because he saw all the rest of the Chirurgians goe that way. It happned that in a hot skirmish so many men were wounded with Gunshot, that all his store of the oyle of *Sambucus* was spent, and many remained to be dressed, whom he was constrained also to dresse, and therefore made for them a Digestiue of whites of egges, oyle of Roses and Turpentine; but as he tels the tale, he was much troubled all the night following, imagining that those whom he had so dressed, he should finde in the morning, either dead, or a dying of their poysoned wounds, because he had not dressed them with the Causticke. Rising very early to visite his Patients, hee found that those whom he had dressed with the digestiue onely were in great ease, and had had a good night, and their wounds were without inflammation or swelling, but the rest who were dressed with the scalding oyle, had Feuers, grieuous paine, and their wounds were swelled, and the parts about them. When he had made experiment of these accidents in many others, he resolued at length to vse the Causticke no more, in which opinion, he was after confirmed by a Chirurgian of great note, who also taught him a soueraigne oyle wherewith he was wont safely to cure wounds made with Gunshot, the receit I haue hereunder set downe. *Recipe Caninos Catulos duos, vermium terrestrium libram unam, olei liliacei libras duas, terebinthina Veneta uncias sex, aqua vite, unciam unam. Catulos vinos in oleum illud coniectos coque quousque carnem ossa descerunt, mox vermes ante in vino albo suffocati, in eodem oleo feruefiant, quoad elixationis vehementia arefacti succum omnem suum in illo decocto remittant. Mox totum id manili transmitto non admodum arcta facta, expressione. Colatis succis terebinthinam adde & denique aquam vite.* Together with the receit, he charged him that he should not communicate it, when *Pareus* came backe to *Paris*, he went to visite *Siluius*, the Kings Professor of Physicke, and amongst their discourse, *Siluius* enquired whether he had learned in his iourney any new method of curing wounds made by Gunshot, and the combustion made in them by the Gunpowder. *Pareus* replied, that there was no venomous nature in the powder, for none of the Simples whereof it was made were poysonous, and beside that he had seene many souldiers take a great quantity of the powder in wine, because they were perswaded when they were wounded, the drinking of that powder freed them from many malignant symptomes. Which course, though he did not like, yet was it argument sufficient vnto him, that the powder was not poysonous. As also because it was obserued that the sprinkling of Gunpowder vpon rebellious Vlcers, bred no symptomes of poysons, but rather did good. As for the bullet, that it was impossible it should conceiue such a heat as should render it Causticall. For if a Bullet be shot against a stone wall, as soone as it falleth from the wall, you may take it vp in your hand without offence, yet a man would thinke it should rather bee healed with the resistance of the stone, then in a mans body. These and the like arguments produced by *Pareus*, *Siluius* perswaded him to write a Treatise of the cure of Gunshot, that the pernicious counsell of *Vigo*, which many men had taken from him vpon trust, and practised to the great detriment of their Patient, might at length receiue redargution. Whereupon *Pareus* applyed himselfe to that businesse, and beside, deuised many new Instruments, whereby Bullets and such like might be extracted out of mens bodies, which Instruments or the most necessary of them at the last, you shall finde deciphered in this following Discourse. But because *Pareus* to giue satisfaction to *Charles* the ninth, and diuers other Princes

Ol Catulorum
Parei.

Princes, hath to his Treatise of the Curing of thote kinde of wounds, præmised an elegant discourse, wherein the nature of such wounds is learnedly handled, I haue thought fit to insert it in this place, for the satisfaction of such as are desirous to heare reason, and are willing to be guided thereby.

*An Apologisme of Ambrose Pary, to Charles the ninth, concerning wounds
made by Gunshot.*

BEing required to render a reason, why the greater part by much, of such as are wounded by Gunshot, did die of their wounds, or at least with much adoe recovered at leasure, yea, though the wounds were not great, and the Chirurgians attended them with all their care, I am bold before my Treatise of the Cure of such wounds, to premise this discourse by way of Apology, as well to satisfie the desires of many Noble personages, as to answer the expectation which may be conceiued of the Kings Prime Chirurgian, which fauour being conferred by *Henry* the second, and confirmed vnto mee by *Charles* the ninth, the worthy sonne of so Noble a Father, I doubt not but many who put too much confidence in their owne iudgements, and doe not intend the narrow disquisition of the causes of things, will wonder and impute it to me for an argument of temerity, that I should stray so farre from the footsteps of learned men who haue gone before me, and strue to cancell their rules and directions; because my opinion is, that the ill qualities which are ordinarily seene in wounds made with Gunshot, doe not proceed from any poyson in the Gunpoulder, neither yet from impoysoning of the Bullet; But I hope that if as men of reason, they will diligently wey my arguments, they will either accord with me, or at least excuse me of presumption, because I intend the common good. But I doubt not to proue by firme reasons, drawne out of the doctrine of the Ancient Philosophers and Physicians, and beside by vncontroulable experiments, as well of my owne, as of other worthy Chirurgians, that the stubbornesse and ill disposition which we vsually finde to accompany these wounds, is not to be attributed to any poyson in the Gunpoulder, or the Bullet, neither yet to any combustion fastned by that poulder vpon the affected part. To begin therefore in order, I will first euict that such wounds are not poysoned, as well because there is in the poulder neither poysonous matter nor quality, or if there were, could they make any impression vpon the wounded part. To this end wee will first examine the composition of Gunpoulder, and see the particulars whereof it is made, their essence, powers, and qualities, and what effects they bring forth, for the simples being knowne, it will not be hard to determine of the nature of the composition. There are onely three simples in this composition; Charcoale made of Sallow, Willow, or Hempe-stalkes; Brimstone, and Salt-Peter. and now and then a little *aque vite*. If you take consideration of every one of these seuerally, you shall finde that they are all free from poyson, or any poysonous quality. The Coale hath nothing in it beside *siccitie* and *tenuity* of substance, from whence it as easily takes fire as Tinder. Brimstone is hot and dry, but not in the highest degree, of a *viscid* and oylie substance, and therefore though it take not fire so soone at the Coale, yet it retaines it better, nor is so soone extinguished. Salt-Peter is so free from poyson, that many men vse it ordinarily in stead of Salt; so that of all the simples in this composition which are with poysonous some suspect, the Sulpher or Brimstone most, though they haue the least reason so to doe. For *Diascorides* appoints Brimstone to be dranke or supped off in an Egge, for such as are troubled with the *Asthma*, with frequent coughings, which spit vp purulent matter out of their Longues, or are troubled with the yellow Jaundise. *Galen* vses it in them that are bitten with venemous Beasts, or are vexed with the Maunge, the dry Scab, or Ring worme, and the Leprosie. *Aqua vite* is of so fine and thin a substance, that if there be any of it in the Gunpoulder, it vanishes as soone as the fire is conceiued; or if it were not, every man knowes how harmelesse a thing it is, either to take inwardly, or to vse in frictions outwardly. It remaineth therefore, that seeing all the parts whereof Gunpoulder is compounded, are free from poyson, the poulder compounded of these parts should haue no poyson in it. And to this euidence of reason, experience also doth suffragate. For the *German* horsemen if they be wounded with Gunshot, doe not doubt to drinke an buncce of Gunpoulder dissolued in wine; and vpon the taking of it, doe promise to themselves immunity from those malignant symptomes, which vsually accompany those wounds.

I will

I will not dispute whether they doe well or no in doing so, but sure they finde no symptoms of poyson to follow, in so much that the *French* souldiers will take it often in a bravery when they haue no need, and that without detriment; yet it is very profitably sprinkled vpon most Vlcers to dry them; & it does the deed. Some there be who being conuinced by these arguments, confesse and acknowledge that the poysonous quality in wounds made by Gunshot, doth not proceed from the Gunpoulder, but from the Bullet which is poysoned. To this I answer, that if there be any such craft or wickednesse attempted, yet the fire dissipates all the force of the poyson, that none of it can remaine vpon the Bullet when it attaines to the marke. And this opinion of mine is confirmed by those things which happed in the siege of *Rouan*. For it is well knowne, that in the Kings Army there were no Bullets poysoned, and the Townesmen when they saw how mortall those wounds were, and immedicable were perswaded the Bullets were impoysoned. On the other side, the Kings Army esteemed all the Townesmens Bullets to be poysoned, because the Chirurgians could scarce cure any of them, they were so euill qualified. Both sides being deceived by assigning a cause according to their construction of the effect. Vnlesse you will vnderstand a pestilent or venemous wound, as *Hippocrates* sometimes vnderstands a pestilent disease, for he calls all diseases pestilent which take their originall from common causes, of what kind soeuer they be, especially if many die of them; because there is in them a malignity proceeding from those common causes, either in the ayre, or in the temper of the heauen, or in the dyet of the people, or the like. For it is to be granted, that wounds made with Gunshot are more obstinate and refractary in their cure, not that they haue any poyson in them, but by reason of some comon viciousnesse in the bodies of men, in the ayre, or disposition of the heauens, or in the corruption or putrifaction of the common viands, all or most of which are very ordinary in populous Armies. And these are the causes which usually make wounds of euill condition, and so obstinate against whole some and fit medicines. I conclude therefore that wounds of Gunshot are not poysoned.

The other question is, whether there be in them any combustion. And first, I know not how it can be conceiued, that Bullets which are made of common Lead, can conceiue so great heat, but that they should melt, whereas we see they passe through Armour, Body, and all, without any signe of liquefaction. Yea, they are so farre from liquefaction, that if they be shot against a stone, as soone as they fall you may take them vp in your hand, and perceiue no heate at all in them. Yet a man would thinke that the violence with which they strike against a stone, should somewhat increase the heat, if there were any. Againe, if there were any fire in the Bullet, being shot into a Barrell of Gunpoulder, it must needs set it on fire, which is against all experience: It may happen that the Bullet offending against iron or stone, may strike fire, and so set the whole Barrell on fire. The like reason there is when a Barne or thatcht house is set on fire by discharging Gunnes against them. For those cunning Incendiaries fasten to the Bullet some Touchwood, or other peece of dry trash, which conceiues fire in the discharge of the Peece, and carries among the Straw, which sets it on fire; or it may be browne Paper, or linnen, wherewith the charge of poulder is rammed downe, will carry fire with it to the house, if it be neere hand. There is also another thing which confirmeth me in this opinion. For if a man shoot a Bullet of Wax which cannot conceiue heat without melting against a boord of an inch thicke, that waxen Bullet will pierce through the boord. It remaineth therefore that the Bullet conceiueth no such heat, that it should burne the wound like a Cautery, either actuall or potentiall. It will be objected that the *Verges* or lippes of all such woundes are blacke, I confesse it, but that is the effect of the vehement contusion; and the contusion is very vehement, as well because the Bullet is round, as because the stroke is so impetuous, that nothing but sense could make a man beleue it. For he that is shot, thinkes presently some huge waight hath fallen vpon him, whence comes a grauatiue pain, & an astonishment in the part wounded, in so much that the naturall heat and spirits are so much dissipated, that the part often Gangrenates. And whereas they say that an *Eschar* falls vpon such woundes; they are deceived, for they mistake for an *Eschar* small portions of membranes, and flesh brused and torne from the rest, which putrifying, are separated by the vigour of Nature, as in all other kindes of vehement contusions we apparantly see.

Notwithstanding these manifold reasons and euidence of sense it selfe doe conuince that there is neither poyson in Gunpoulder, nor combustion from the Bullet, yet there are some which seeme to themselves, at least would seem to others to haue arguments against this truth built vpon naturall principles.

The

The report of the Canon (say they) is like the lightning and thunder which breaketh out of the cloudes in the middle Region of the ayre, and are precipitated vpon our world, and therefore the Bullet must needs as the thunderbolt, be poysonous and causticall. I am not ignorant that the lightning which is ingendred of a crasse and viscous exhalation, when the cloud wherein it inuolued is broken in sunder, neuer falls vpon the earth, but it carries fire with it, sometime more subtile, sometimes more crasse and materiall, according to the differing condition of the matter from whence the exhalation did proceed. For *Seneca* Quest. Nat. lib. 2. ca. 49. writes, that there are three sorts of Lightnings which differ one from another in the inflammation, in the kinde, and in the plenty. The first is, that which by reason of subtilty and thinnesse of his matter, penetrates that which withstands it; as it were, by perforation. The second is, that which with impetuous violence disheuers and dissipates whatsoeuer it meets with, because the matter of that fire is more dense and compact, and his course more rapid, furious, and contorted. The third is made of a more earthy matter, and burnes where it touches, and leaues behinde it footsteps of his adustion. I know also that all Lightnings is of a pestilent nature, and the two last kinds foetid also, because of the viscous crassament, which being set on fire, exhales an odious odour, wherewith the very wilde Beasts are so offended, that if it fall neere their dennes, they will forsake them. And *Olaus Magnus* in his Northerne History, saith, that they runne farre and wide after a Lightning is strewed with Brimstone, but doted and extinct, which otherwise is a quicke and *viuid* Minerall. But it doth not follow hereupon that the shot of a Canon or Musket transferres poyson, or fire into the wound it makes. For though the Canon and the Lightning be in many things alike, yet the likenesse holds not in the matter and substance, but onely in the impressions they make vpon the bodies which oppose them, those they equally rend and tear, dissipate and demolish; the Lightning by the violence of fire, and sometimes by the thunderbolt; but the Canon by the rapid agitation of the Ayre, whereby the Bullet is furiously transported. Or if it should be granted that the matter of them both is alike, yet it would not follow that the Bullet should conceiue or retaine any fire. For according to *Pliny*, there are some Lightnings which being composed of a matter exceeding dry, do indeed shatter all things that oppose them, but burne not at all. Others which being of a moyster Nature, do soyle & make blacke, but burne no more then the former. Finally, there are other Lightnings of thin and subtile Nature, which kinde *Seneca* esteemes to be Diuine, because they will melt money in a mans purse, but the purse they will not burne, in like manner they will melt a sword in the Scabbard, but not offend the Scabbard at all with any appearance of combustion; All these kinds of Lightnings a man may imagine to be of like substance with the stroke of a Canon. But not those which carry fire and flame on their wings. To exemplifie this truth. I remember I once drew out of a Souldiers thigh, a Bullet which was rolled vp in a peece of his Cannions, the cloath was of a fine wool, yet sound and not at all scorched. Againe, I haue knowne many whom the Bullet nor the Poulder euer toucht, but flying neere their heads, hath stricken them downe in an astonishment; yea, some whose flesh hath presently growne liuid and blackish, vpon which hath followed a Gangreane, whereof they haue perished. These and the like accidents to these, doe neereley resemble the effects of those Lightnings whereof I spake euen now, and yet are without shew of poyson. I conclude therefore that the stroke of Gunshot doth neither impoyson nor burne the part. But because in these last Warres, the wounds of Gunshot proued so refractary and mortall, as well to those of the Nobility, who had as much meanes as could be imagined, vsed for their recovery, as to the common souldiers: It is necessary I should vnfold the true causes of that contumacy and mischief, seeing I disauow the causes which were commonly receiued, to wit, poyson and combustion. For the better explication whereof, I must take my beginning from the mysteries of Nature, and the principles of Philosophy.

It is therefore confessed on all hands, that there is a sympathie of the foure Elements, whereby they are so disposed, that they easily suffer transmutation one into another: A transmutation, I say, not onely by a vicissitude of the first qualities, that is, of heat and cold, drought and moysture, but by rarefaction and condensation their proper substances are commuted, so that fire is turned into ayre, ayre into water, and water into ayre, waer also into earth; and contrariwise earth into water, water into ayre, and ayre into fire; the reason is, because those first bodies, being made of a common matter, are furnished with contrary qualities, which being the first qualities, are also most potent and efficacious in their kinds. An example of this we haue in the *German Scelopylis*: An instrument made of
brasse,

brasse, hollow and writhen, and determining in a narrow point, into which when water is conveyed, and that point held neere the fire, the heate thereof rarifies the water into fyre, which because of the contorsions, finding not a free gresse breakes out with murmour and noyse. The very same thing you may obserue in parching of Cheasnuts, put them whole into the fire, and suddenly they will cleaue with a great cracke, the reason is, because the waterish moysture contained in them, is by the heate and actiuity of the fire, rarified into ayre which breakes a way for it selfe. For water being so rarified into ayre, occupieth a greater place then it did whilst it was water, and therefore cannot be contained with the skinnes of the Cheasnut as it was before, but forces a passage for his liberty. After the very same manner Gunpowder being set on fire, extends it selfe into a farre greater proportion of ayre, and some limit the proportion thus. One part of earth makes ten such parts of water, one part of water makes ten of ayre, and one of ayre ten of fire. Wherefore that ayre when it cannot be contained in the barrell of the Peece wherein the Powder was contained, makes way for it selfe with impetuous violence, and driues the Bullet before it, and giues the report; yet so as that it instantly vanishes into the ayre adjacent, so farre is it from attaining to the marke at which the Bullet arriues. Notwithstanding we say that the Bullet it selfe doth so inforce the ayre it meetes withall, especially if it be the Bullet of a Peece of Ordnance, that that very ayre so vehemently in force, will breake a mans bones without breaking the flesh, and therein it is like the Lightning as I said before.

Another experience hereof we haue in Mines, wherein Gunpowder being set on fire and turned into ayre, will blow vp a little mountaine of earth. In the yeare 1562. a proportion (not very great) of Gunpowder, conceiuing fire in a Magazine, made such a thunder as shaked the whole Citie, but the houses which were neere it ouerthrew to the ground, those that were further off it dismantled, broke all the windowes, and like Lightning in a Storme, some mens breath it strooke out of their bodies, some lost their eyes, some their hearing, some mens members were torne off, as if they had been rent with wilde horses; and all this onely by the agitation of the ayre, into which the Gunpowder being set on fire, was conuerted. Like as we see when wind is concluded in the bowels of the earth, which want vent for it, it rages about the conceptacle, and shakes the sides of the earth, and produces an earthquake. And many times it heaues it vp, or sinkes it downe, or which is most strange, transports it to another place. So we reade, that *Megara* and *Agina*, sometimes famous Cities of *Greece* were demolished and swallowed by an Earthquake. These things being premised, wee come now to accomodate them to our present purpose. Among those things which are necessary for the life of man, there is nothing which makes so many alterations or so great, as the aire, which we continually draw into our bowels, as well by inspiration, as by transpiration, whether we wake or sleepe, whether we labour or be at rest. Whereupon *Hippocrates* giueth it the title of Diuine, for it imbraces, nourishes, defends, and tyeth, as it were, in a band of concord and agreement, whatsoever is contained in this lower world, wherethrough it breathes. Moreouer, it also consents and agrees friendly with the influences of the starres who are partakers of Diuine virtue and efficacie. For these influences making alteration in the ayre, doe thereby impress a necessary mutation vpon the inferiour world. Hence it is, that Physitians and Philosophers when they would giue precepts, either for the maintayning of mens health, or the profligating of diseases, doe command vs religiously to obserue the sites and dispositions of places, and the constitutions of the ayre. And that the ayre hath a great command ouer the world, appeareth by the foure seasons of the yeare. For in the Summer, the ayre being hot and dry, doth likewise heate and dry mens bodies: in like manner, the cold and moyst Winter, makes the body coole and moyst, and brings forth consimular effects, yet with that temper, proportion and moderation, that the variety is within the limits of health, if the seasons keepe their seasonableness; but if they depart therefrom, that is to say, if euery season doe not answer the lawes which Nature hath imposed vpon it, but trench vpon the temperatures of other seasons, then arise many and potent perturbations, not onely in the bodies, but in the mindes of men also, and the impressions of that obliquity and preuarcation it is not possible to auoyde, because the cause is ambient and entred together with the ayre into the secretest corners of bodies, as well by the blinde pores of the skinnes, as by the open and direct in-draughtes. Particularly for the winds, the South-wind is hot and moist, the North, cold and dry, the East-wind is briske and cleare, the West contrary, turbulent and nubulous. Can any man then imagine but when the winds so seuerally qualified, doe

raigne,

raigne and domineere in the ayre, which we continually inspire and expire, but that it is of necessity that those mutations should affect our inward parts? Hence it is, that *Hippocrates* obserued that the commutations of seasons, whether they proceed from the winds, or from vnseasonable vicissitudes, are the especiall authors of diseases. For example. A Northern constitution of the ayre, firmes and fastens the body, makes it agile and nimble, giues it a fresh colour, and quickens the hearing. All this it performes by rowzing and vegetating the naturall heate. On the contrary, the Southerne constitution dissolues the powers of the body, and moystens the whole frame, duls the head, amazes the hearing, makes men giddy, and turne-sicke; listles also, and heavy-ey'd, all which inconueniencies the *French* of *Languedocke* are too sensible of, and yet they are seated amongst the most deliuer and active of the *French* Nation. In summe, if you compare the seasons and constitutions one with another, you may conclude, that generally the dryest are most wholesome and lesse dangerous; to wit, because too much moysture is the mother of putrifaction, as may be perceiued by those that liue vpon the Sea-coast, for the winde which comes from Sea, makes those Vlcers which would easily be cured, become more stubborne, by reason of the multitude of *Sordes* which they gather. Beside, the flesh that is there killed for mans vse, will putrifie in an howre. I thinke a better reason may be giuen hereof: As therefore when the seasons of the yeare are seasonable, according to the vicissitudes of the Law of Nature, either there will be no popular diseases at all, or else they will be lesse dangerous: So if they be not correspondent, but distempered and peruered, the Symmetry of mens bodies is dissolued, and sicknesses either rush or steale vpon them. Whereas therefore, for diuers yeares now past, the foure seuerall seasons of the yeare haue been vnseasonable, the Summer wanting his heate, and the Winter his cold, and the Southwinds so frequent, that all things haue abounded with superfluous moysture, whereby the strength of Nature hath languished, and beene dissolued, I beleue that any man skilfull in the course of Nature, and the affections of the Heauens, will easily referre the malice and contumacy of these diseases wherewith *France* hath been a long time trauailed vnto these inordinate dispositions of the Ayre and the Heauens; From whence trow-we-else could so many pestilent and contagious diseases proceed, wherewith all Ages, Sexes, & conditions of men haue bin afflicted? Whence came the popular Murres and Poses, the Hoarsenesse, Pleuresies, Tumors, small Pockes and Meazels: Itchings also and Breakings out, which no Medicine could concoct and mitigate? Adde hereto many sorts of venomous creatures, Toades, and Frogges, Grasshoppers, Wood-seare-wormes, Spiders, Gnats, Waspes, Hornets, Beetles, Dew-Snailes, Vipers, Snakes, Lizards, Scorpions, and the like; All which are bred out of Putrifaction, putrified and actuated by an euill disposition of the superior bodies. Hence also came the weakning of mens naturall heate, whereof their spirits and humours being destitute, did runne into corruption, which also was increased by many foultry Southwinds. And therefore the blood that I haue let by the appointment of Physicians, in these yeares by-past, hath had for the most part a Character in it of putrifaction, to wit, a liuid or greenish colour, and that not onely in such as haue beene sicke, but in those also which haue beene let blood for preuention of sickness. If therefore the blood and humours were so corrupted, it must needs follow, that the flesh which is made and amassed of them, must needs be vicious, as well in temperature, as in the consistence. And hence in deed, and from hence onely it was, that the wounds wherein some part of the flesh was taken away, did hardly re-vnite, or not at all, because that should haue restored it, was ill-disposed. So we see that such as haue the Dropsie, whose blood is cold and waterish, and such as are leperous, whose blood is corrupted, if they happen to haue any Wound or Vicer, *Vix autne vix quidam curantur*, as *Hippocrates* saith. Yea, if a body be any way Cathetickall, or of ill-habit, the Wounds and Vlcers of such Bodies are hardly cured. And not onely so, but if any part of the body hath lost his naturall temper, and receiue a wound, that wound wil be very hard to cure. But if all these potent causes conspire together, that is to say, the indisposition of the aire, the putrifaction of the humours, and the distemper of the parts, what wonder is it, if the wounds which were not great, even in fleshy parts, in these last ciuill warres, proued dangerous and full of euill accidents; yea, many times mortall? I my selfe can witnesse, that in the cure of those Wounds, there arose from them such a stench (the most certaine signe of Putrifaction) that the standers by could vneath endure it. Neither could this stench be attributed to the fault of the Chirurgian, or to any want of good meanes in the progresse of the Cure, for the stench was all one in the wounds of the greatest Com-

manders, and of the poorest Souldiers. Yea, the corruption was so great, that if a wound did escape dressing but one day, (as in such a multitude it might well happen) the next day it would be full of wormes. Moreouer, (which doth further proue the height of the humours putrifaction) it was often seene, that Apostemations would arise in the parts opposite to those that were wounded, for example, if the right Shoulder-blade were wounded, the left Knee would apostemate, and the left Arme if the right Legge were wounded; which very thing hapned to the King of *Nanarre*, the Duke *Neuers*, and the Lord of *Rendan*, and many others. In a word, All mens Natures were then so surcharged with the burthen of vicious humours, that it was necessary some part of them should either bee amanded into the habite of the body, and there Apostemate, or bee otherwise thrust into the more noble parts: for in those bodies which were dissected after death, a man should finde sometimes the liuer, sometimes the spleene, sometime the longues, sometime other of the bowels purulent. From these Lee-stals the vapours being eleuated to the heart, bred continuall feuers, and because the liuer and all the yeines were so defiled that they neither could breed nor did containe laudable blood, the body grew into an *Atrophie*; the braine was drawne into consent by the vapours which arose vnto it, and thence came phrensies and convulsions. If therefore the cure of wounds in such bodies proved vnprosperous, it was not to be imputed to the Chirurgian, but to be ascribed to Almighty God, and vnder him to the ayre, in which his scourges were disposed. I conclude therefore according to *Hippocrates* his opinion, that all wounds with contusion must be brought to suppuration, or else they cannot be cured; which course, if we held in wounds made by Gunshot, who can iustly accuse vs, though the successe did not answer our expectation by reason of the frequent Putrifactions, Gangrenes, and mortifications which hapned through the fault of the ayre. Yet did we not fight onely with that weapon of suppuration, but with diuers other medicaments and instruments to abate and ease those symptoms which threatned the liues of our Patients, of which we will intreat more particularly in the following discourse.

CHAP. XXIII.

The diuision and signes of Gunshot wounds.

THe wounds made with Gunshot are either more simple or more compound; We call those more simple which haue fewest symptoms, those more compound, wherein there is greater contusion, laceration, distemper or Tumor. If the Bullet light in a fleshy part, and therein determine, and no notable vessell be broken, the wound is more simple and will be cured wellnigh as easily as a wound made with any other weapon that wounds with contusion, for contusion lesse or more is common to all wounds of Gunshot. But if the contusion be notable, the laceration great, if any bone be broken, if any notable vessell be violated; finally, if there be any great distemper or tumor succeeding the wound, then is the wound more compound, and the cure of such symptoms doth many times diuert the Chirurgian from his course of suppuration, till he haue provided for that which vrages him more. Again, sometimes the wound is but superficially or descends not deepe, sometimes it penetrates farre, sometimes it goes through and through the body, and according to those varieties the cure is more easie or difficult. Moreouer, there is great difference in Bullets, some are great, some little, some betweene both: some are, as we call them, but Haile shot; allos them round. According to these differences the Chirurgian must fashion himselfe and vary his medicaments. Alwayes remembring that which I haue said before, that he impute not the many symptoms which follow this kind of wound to any poyson, or combustion, but to the vehemence of the contusion, laceration, or fracture made by the impetuous force of the Bullet.

For the signes, there is one generall, that the wound is orbicular or round: the Colour also of the part is altered and become liuid, blewish, greenish, or betwixt both. Adde hereto that the sense of the blow is grauatiue, as if some huge weight had fallen vpon the part: neither doth the blood issue proportionably to the wound, for the parts being sore brused, doe presently swell, in so much that you can hardly insinuate a pledget into it, for the lips of the wound being tumified, hinder the issue of the blood. There is also in this kinde of wound, a very great heate, caused either by the swiftnesse of the motion, or by the vehement impulsion of the ayre, or else because the contused parts being driuen one against another, raise heate by attrition. The reason why a Bullet makes so great a contusion, is, because

because it hath no corners to cut his entrance but is round, and therefore cannot enter without extreame force, and thence it is that not the wound onely is blackish, but the neighbour parts also are liuid. Hence also proceed those many ill symptomes of paine, fluxion of humours, inflammation, apostemation, convulsion, phrensie, palsie, Gangrene, mortification, and at length death it selfe. The contusion also and the rending attrition and tearing of the adjacent parts, make the sanies or matter of the wound which it belcheth out, to be of a noysome and odious saour, and so much more plentifull, because to a part so notably offended many humours will flow out of the whole body, which at the part affected cannot be gouerned by the weakned naturall heate thereof, and therefore rot in corrupcion. But if you adde to this confluence of humours, whereby naturall heate is suffocated, those other vniuersall or particular causes of putrifaction in the ayre, and in diseased bodies, then wil the matter or sanies be as neere a poyson as putrifaction can attaine being exalted, and consequently the stench and other symptomes more dangerous and mortall. Now I proceed to the Cure.

CHAP. XXV.

what must first be done in the cure of wounds by Gunshot.

Soone as a Chirurgian is called, he must first of all enlarge the wound (if the condition of the part will suffer him) as well that the sanies or matter may more freely issue, as also that he may more easily get out any thing which was thrust in with the Bullet (as ragges, towe, Paper, peeces of Harnesse, and the like) or the Bullet it selfe, broken splinters of bones, or brused flesh, all which with as much expedition as may be, must be drawne away, for in the beginning the paine and inflammation is not so great as it will be afterwards. For the better performance hereof, the Patient must be put into the same posture wherein he was when he received the wound, otherwise the conuersion of the muscles wil either wholly interclude and shut vp the passage by which the Bullet entered, or at least make it much narrower.

Now those strange substances of what kinde soeuer they be, which are contained in the wound, must be sought for, if it may be with the finger, for that is a more certaine search then with the Instrument: yet if the Bullet goe deepe, the Instrument must be vsed, to wit, a probe round, and obtuse, yea, a little butned at the end, that it may enter without paine; with such an one the Chirurgian shall try if he can finde the place where the Bullet is couched: yet hath it beene often seene, that what the Instrument could not finde, the finger hath discovered, obseruation being therewithall made, where the paine, where the hardnesse, where the Tumor, and finally where the flesh was liuid and discoloured.

The den of the Bullet being found, the next care is how to get it out: That must be done by an Instrument made for the purpose. Of these instruments there are diuers formes in vse amongst Chirurgians, all which must be at hand to answer the variety of the Bullet, or the part wherein it is lodged. For a Chirurgian must fit his instruments to the part, and to the wound; he must not fit the wound to his Instruments.

These instruments framed to draw out bullets or other strange substances out of wounds made by Gunshot, are almost all called by one generall name, *Bills* or *Beakes*, as the Crowes Bill, the Cranes Bill, the Drakes Bill, the Parrots Bill, and the Swans Bill. One other there is made like the head of a Snake, and another headed like a paire of Moulds, wherein Pistoll Bullets are cast. The descriptions of them all you haue hereunder exprest with their particular names, that the Chirurgian may make his choyce according as the present occasion shall admonish him.

The toothed Crowes Bill.

The crooked Cranes Bill with the teeth like a Saw, you shall finde described in the next Page following.

There is also a Cranes Bill which is straight, whose inside is rather rough and vnequall, like a Smithes File, then toothed or indented like a Saw, and that is fittest to draw out Haile-shot, small Plates, sharpe splinters of bones and such like, which are deepe in the flesh. And if these things require an instrument which will hold somewhat faster, then the Chirurgians may vse one somewhat broader and more vnequall in the insides and a little hollowed which is very properly called the Drakes Bill, to which it is very like. These two instruments need not be disciphered, for any man may easely imagine how they should be made.

If the bullet be rounder and larger, then the Moulds are to be vsed, made after this manner.

The head must be like the head of a paire of moulds, the body must be round and hollow, and is in the figure marked with *A*. Through that hollow body runnes a probe of iron marked with *B*, with a vice at the top like the vice of a pompe marked with *C*, which drawes vp the bucket; therefore with a pin is fastned one side of the mould head which is moueable, so that when the probe is thrust vpward the head of the mould opens, when it is drawne downe the mould closes and holds fast the bullet till all be drawne out of the wound together. The instrument called the snakes head is made after the same manner, sauing that the head of the Mould is round and the snakes head is flat and depressed, and therefore it need not here be delineated, the vse of it is when the bullet is flatted a little and hath lost his compasse. Somewhat different is the instrument called the Parrots Bill, and serues best to draw out any small peeces of Armour, Mayle, or whatsoever else the violence of the shot shall breake off and carry before it into the flesh or the bones: and therefore you haue the figure of it here exhibited.

A, Sheweth the handle of the vter screw:

B, the trench or hollow screw in which the vter screw is inserted, to which it is fitted, & wher-

in it is turned. *C*, The moueable shaft or spindle which the vter screw eleuateth and sinketh. *D D*, a double part in the immoueable hollow trunke, which hath a Beake like a Parrot at the end, whence the instrument hath his name, and this hollow trunke and the parts therein, doe gouerne the motion of the shaft or the spindle.

There

There is also another Instrument called the Swans beake, the sides whereof are opened by a screw when it is insinuated into the wound and so the wound is dilated; then they haue another slender instrument called the Cranes beake mentioned euen now, with which as with a payre of pincers, they take any thing out of the wound so dilated: the figures of both which are here vnder expressed.

But if those strange bodies which are driuen in, whether it be one bullet or hayle-shot, do not descend deepe into the wound, they may be gotten out with a small peircer serued at the end, and compassed about with a hollow cane of iron; which sharpe screw shalbe turned till it get hold of the lead, and so it may be drawne out. And thus much shall serue concerning the extraction of bullets, bones, peeces of iron, and other strange substances which are driuen into wounds.

Now to search where those strange substances lye in the wound (for the lippes of the wound presently vpon the stroake will close together) the Chirurgians vse a Probe, round and smooth, with a smooth button at the end, and so long that it may reach to the bottom; for being smooth and buttoned, it will not violate the flesh in the search. The same Probe also they make with a needles eye, that if the wound bee through and through they may draw a seton or a flamula through it, which they annoynt with medicines fit for their purpose: or if the wound bee not altogether but neere through and through, so that the bullet cannot bee drawne out where it went in, then the button of the needle serues to discover what distance there is of flesh betweene the bottom of the wound and the contrary side, and if it be not much, they make incision, and so take out the bullet; and when that is done, they draw a seton or flamula through to facilitate the cure. So that this Instrument serues for a double, yea a trible vse, and therefore you haue the description of it here vnder expressed.

And so much for
the finding & draw-
ing out of the bul-
lets.

CHAP. XXVI.

Of the first dressing after the Bullet is drawne forth.

When the Bullet or whatsoeuer strange substance is thus extracted, the next part of the cure is to minde the contusion by suppurations, such as is the oyle of whelps, vnlesse there be feare of a gangrene, either because of the constitution of the ayre, or the condition of the part affected. Moreouer, if the part wounded be neruous or neere a ioynt where the tendons of the muscles are fastned, then in stead of oyle you shall vse *Venice Terebintine*. Adde also that which *Ioubert* hath concerning wounds of this nature, that you must beware of such hot medicines as we call *escharotica*, (though they be not *Cauticks*) as well because they induce payne, inflammation, feuers, the gangrene and other like mortall symptomes, as also because when an eschar is made in the wound, all sup-
puration is prohibited which is most necessary in this case, for by suppuration the contused flesh is separated from that which is sound, which otherwise by contagion will bee also drawne into putrifaction. Moreouer, when the excrementitious humor is concluded by the eschar as by an obstacle, and resteth in the part affected, then the putrified vapours arising therefrom not hauing issue, are multiplied, transmitted, and diffused from the lesser vessels into the greater, and from them into the whole body. Wherefore when you haue reason to suspect any putrifaction in the wound or forward inclination thereto, you shall doe well to forbear suppurations and fly to medicaments which resist putrifaction, such as is the vn-
guent following called *Egyptiacum*.

R. Pulueris Aluminis Roche, viridis aris, vitrioli Romani, Mellis rosati, ana uncias duas; aceti optimi quantum sufficit, bulliant omnia simul secundum artem & fiat medicamentum ad formam mellis. The heate and subtile substance of this medicine affordeth it a facultie to cut and attenuate humors. It also recalls and establishes the naturall heate of the part which was afflicted and dissipated by the rapid and violent impulsio[n] of the bullet into the body; and besides it corrects the virulencie and contagion of the humor transported by the Contusion so far beyond his nature that it draweth neere the nature of poyson it selfe.

You shall therefore vse this medicine dissolved in vinegar or in *aqua vita*, and therewith annoynt your tent or the seton in the Chapter before spoken of, or the flamula. And at the first dressing you shall make your tents longer and thicker; longer, that they may attayne to the depth of the wound; thicker, that the wound being thereby dilated, way may be made for other medicines as cause shall require. But if the tent make not way sufficient, you may with a small syringe cast in what you thinke fit: yea this medicine it selfe being so dissolved, may be squirted in that it may search the bottome of the wound; obserue onely that in neruous parts you contemper this medicine with an admixtion of the oyles of *Terebintine* and *Hypericon*. But if there be no suspicion of putrifaction, nor the ayre be inclined to a pestilent Constellation, you may forbear this medicine, & in stead of it apply remollient and lenient, such as is the oyle of whelps before mentioned, which is thus confected.

R. Olei violacei libras quatuor, in quibus coquantur Catelli duo nuper nati vsq[ue] ad dissolutionem ossium, addendo vermium terrestrium vt decet preparatorum libram vnā. Coquantur simul lento igne, deinde fiat expressio ad usum addendo terebintina Veneta uncias tres, aqua vita vnciam vnā. It must be applyed warme, and then it hath a wonderfull vertue to ease paine, to hasten suppuration, and to loosen an eschar: but because this medicine cannot alwayes or easily be gotten, in stead of it you may vse this following.

Recipe Oleorum semin. Lini & Liliorum ana uncias tres, vnguenti Basilici vnciam vnā: liquefiant simul & fiat medicamentum. Of this you may issue into the wound as much as you shall finde to be fit: for being a little warmed, it eases paine, it supples and moystens the lips of the wound, and brings forward suppuration mightily, which is the mayne intention of all in these kindes of woundes, because all contused flesh must and ought to be suppured, that new and solid flesh may be restored in the roome thereof. *Ioubert* commends the medicine following, which yet *Pareus* had not made triall of when he wrote this Treatise of Gunshot.

Recipe Pulueris Mercurij bis Calcinati vnciam vnā, adipis porci recentis vel butyri recentis uncias octo, Camphora in aqua vita dissoluta drachmas duas, misce omnia simul addendo tantillum olei liliorum aut lini. Forsooth reason and experience both taught *Ioubert*, that this was an excellent medicine. For the poulder of Mercury, when it is mixed with a crasse and moyst matter, will in a short time turne Contused flesh into quittance, and yet procure no great payne. As for the Camphire, it is of exceeding subtile parts, and therefore doth not on-
ly

ly it selfe penetrate but is also a vehicle to transport other medicaments that they may more freely operate according to their virtues. Adde hereto that Camphire doth mightily resist corruption and putrifaction.

Now if the wound be giuen at hand and neere a man, it cannot be but it must be scorched because of the flame of the Gunpowder, and therefore in such a case the Chyrurgian shall vse such medicaments as are fit for that kinde of affect, and yet not neglect suppurations. As for those parts which touch the wounded part or are neere neighbours to it, I would not aduise that refrigerant and adstringent medicines should be vsed to them, vnlesse haply in the first dressing, for those that coole weaken the part and hinder suppuration; those that are adstringent doe constipate or close vp the pores of the skin, which is the cause that (the putrid vapours being concluded so that they can neither issue nor expire) the part Gangrenates and morrifies.

Moreouer, if the Contusion be notable so that much flesh about the wound is brused, then it wilbe fit to scarifie it manifold and deepe, that the part may be vnburthened of that brused and clodded blood, which if it subsist will easily degenerate into putrifaction. As for the parts which are farther remote from the wound and doe compasse the Contused flesh; it shalbe behoofe full to apply to them refrigerant and corroborating medicines which may stay and inhibit the defluxion of humours vnto them, such as is that which followes.

Recipe Puluer. Boli Armen. sangui. Dracon. pul. Myrrha, ana unciam vnam succorum solani, semperuini, portulacae, ana unciam vnam semis. Albumina quatuor onorum, oxymorodani quantum sufficit, fiat linimentum vt decet. This and such like you may vse till the feare of accidents or symptomes is ouer blowne.

Finally, there is no lesse care to bee had of the fitt binding of such wounds then there is of the medicines. Aboue all labour to place them in an indolent situation, dresse them not aboue once in 24 houres at the first, til the quittance begin to issue, afterward dresse twice a day that is once in 12 howres. but when the quittance flows abundantly so that it is troublesome to the patient, dresse every 8 houres: againe when the quittance begins to faile dresse every 12 houres, when the vlcer beginnes to fill with flesh once in 24 houres as at the beginning, and thus much of the first dressing.

CHAP. XXVII.

Of the second dressing.

IN the second and subsequent dressings (vnlesse there be a suspicion of putrifaction, or that the wound should Gangrenate (the cure whereof wee shall intreate of afterward) you shall poure into the wound onely some of the aforesaid oyles, adding thereto the yolkes of egges and a moment of saffron, and that so long till the excrement of the wound be concocted into quittance, which will be longer then is vsuall in other kinds of wounds not made with Gunshot, because not the bullet onely but also the ayre which the bullet impetuously driues before it, by braying the flesh as it were dissipates the natural heate and exhausts the spirits of the affected part, so that nature cannot hasten her worke of concoction; besides the stench of the sanies and other dry symptomes which follow vpon the Contusion breake her powers and interturbe her operation. Notwithstanding oftentimes about the third or fourth day, quittance will appeare sooner or later according to the complexion and constitution of the body, and the condition of the ayre: Thence forward you shall vse deterfues adding to your former medicament some Turpentine washed in rose water or barley water to abate his biting quality. If the season be very cold you may do it with aqua vita, or adde a little of it to the other. Your detergent medicine make after this manner. *Recipe aqua decoctionis hordei quantum sufficit, succorum plantaginis, apij, agrimonie, Centaurij minoris, ana unciam vnam; bulliant omnia simul; in fine decoctionis adde Terebinthine Venetae uncias tres, mellis rosati uncias duas, farina hordei drachmas tres, Croci scrupulum vnum: misceantur omnia simul bene agitando, fiat mundificativum mediocris consistentie.* Or, *Recipe Succorum Clymeni, plantaginis, Absynthij, apij, ana uncias duas. Terebinthine Venetae uncias quatuor, syr. absynthij & mellis rosati, ana uncias duas; bulliant omnia secundum artem, postea colentur, Colatura adde puluer. Aloes, mastich, Ireos florent. farina hordei: ana drachmam vnam: fiat mundificativum ad vsum dictum.* Or, *Recipe Terebinth. Venetae lota in aqua rosarum uncias quinq, olei rosati, unciam vnam, mellis rosati uncias tres, myrrha, aloes, mastich, Aristoloch. rotunda. ana drachmam vnam semis, farina hordei drachmas tres: misce, fiat mundificativum.* Which medi-

medicines you shall vse with tents neither too long nor too thicke, least the tent hinder the issue of such vapours as are rayfed in the wound. For if those vapours be intercluded, the part wounded will be gnawne (as it were) with their sharpenesse and acrimony, whence will follow paine, new fluxion, inflammation, hollownesse in the vicer, putrifaction and the like; all which will not onely afflict the part affected, but also be communicated to the whole body: but if so small tents as you must vse will neither pertaine to the bottome of the wound, nor keepe it open till the strange substances and the quittance are excluded, it will bee very behoofefull in such sinuous and profound wounds to vse such an injection as followeth.

Recipe, Aqua hordei Libras quatuor, agrimonia, Centaurij minoris, pimpinella, absynthij, plantaginis, ana semimanipulum: rad. Aristolochia rotunda semi-drachmam: fiat decoctio ad libram unam. In Colatura expressa dissolue Aloes hepatica drachmas tres, mellis rosati uncias duas, bulliant modicum. This decoction you shall inject into the wound three or foure times euery dressing, and if that will not deterge the sanies sufficiently and consume the spungie, putrified, and dead flesh; you shall dissolve in your decoction as much of the *Agiptiacum* described before as you shall thinke fit: put case an ounce of the *Agiptiacum* to a pound of the decoction, for so it will eate out the spungie flesh which growes in the hollownesse of the wound, and inhibite the growth of true flesh which is not fit before the wound be sufficiently clenfed. For which end also (saith *Pareus*) I haue had experience, that the poulders of Mercury and burn'd Alume mixed in equall portions are very excellent. Many practitioners doe vsually suffer a great part of this decoction to remaine in the cavity of the wound, especially if it be sinuous; which *Pareus* worthily disalloweth, as well because the liquor remaining makes a tension or stretching of the part affected; as also because being so ouer moystened, the flesh will not so promptly be regenerated; for it is a rule in Chyrurgerie, that euery vicer as it is an vicer ought to be dried as much as may bee, and he that can dry an vicer can cure it. It is also ordinary for Chirurgeans to offend in the too frequent vse of setons or lines of hayre. For changing them often and drawing them vp and downe in the wound, they hurt the tender sides thereof, bring paine vpon the Patient more then needs, and exasperates the malady, which thereupon produces many maligne symptomes. Wherefore my counsell is (saith *Pareus*) that if the wound yeeld much matter or quittance, that the Chirurgeans vse hollow tents, so that the sanies may issue oftner then it is drest, and so Nature will be releued with lesse trouble. He also vseth to presse double ragges vpon the bottome of the wound if it can well be com'd vnto, to drinke vp the sanies, and to presse the parts a litle together, that the matter may issue; but let the Chirurgeon take heede he leaue none of the cloute in the wound: the double clothes also which he layeth ouer the orifice of the wound and vpon his hollow tents, would haue a large perforation in them, at which perforation hee may place a peece of soft sponge, to receiue the quittance as it issueth.

Now for the binding or rowling vp of the wound, the first care must be that it be not too straight, for that will inhibit the issue of rotten vapours and excrements which the bruised flesh yeelds; beside it will endanger to bring an Atrophy by keeping the alimentary iuyce from the part. Next you must take care to begin to rowle from the bottome of the wound, and so proceede to the top or orifice; for that manner of rowling leades away the quittance better. Lastly, you shall wet your clouts and rowlers with *Oxycratum* or hard wine, for that will adde strength to the part, and beside intercept a new flux of humours.

And because it happeneth many times that by reason of the vehemencie of the Collision the bones are shattered into small peeces, which at the first dressing cannot bee gotten out but remaining in the wound doe goade it greuously; I haue added an excellent and approved remedy to bring away such remainders out of *Pareus*.

Recipe, Rad. Ireos Florentia, panac. & Cappar. ana drachmas tres: Aristolochia rotunda, manna, thuris, ana drachmam unam. In pollinem redacta concorporentur cum mellis rosati & terebinth. Venet. ana uncias duabus. Or, Recipe, Resina pini sicca uncias tres, pumicis combusti & extincti in vino albo, rad. Iridis, Aristolochia, ana semidrachmam, thuris drachmam unam, squamma eris drachmas duas. In pollinem redigantur, diligenter incorporentur, cum melle rosato fiat medicamentum.

CHAP. XXVIII.

What remaines afterward for the Chirurgeon to doe.

When the skilfull Chirurgeon hath gotten out the strange substances out of the wound, and cleansed and purged it of the sanies and quittance which the Contused flesh did yeeld, so that now the wound growes dry, then he shall employ all his care to regenerate new flesh and draw a Cicatrice vpon it. Now because that is the worke of Nature rather then of medicine, therefore he shall take counsell of the learned Physitian how to institute his diet, how to physicke his body, how to proportion the cure according to the temper of his Patient and of the affected part, with such other indications as we vsually gouerne our selues by in the like cases. For the Chirurgeon shall often finde himselfe at a losse by reason of the variety of the ambient ayre and disposition of the yeare, the age, temper, and custome of his Patient, the noblenesse and sence of the part affected; to say nothing of the complication and composition of infirmities, and many other particulars which to recite belongeth not to this place. In one word, hee must endeavour two things especially: the first is that the part affected be restored to his genuine and native temper: the other is, that the masse of blood doe not offend either in quantity or quality. For if these two be right, nothing else can hinder the regeneration of solid and good flesh, and consequently the vnion of the wound. Neither toward the end onely, but from the beginning almost of the cure, the Chirurgeon shall neede the Physitians aduise for institution of diet, for oportunitie of purging and letting of blood, for easing of paine, yea in the mayne scope of the cure of the wound, good direction for vulnerary potions, will be of great vse. To say truth, a Chirurgeon cannot walke safely alone without the helpe of a Physitian in any cure almost which he takes in hand, vnlesse he be a peece of a physitian himselfe: which skill as it is ordinary in Chyrurgeans of other Nations, because they be all or most of them Schollers; so amongst vs where men get their skill in Chirurgery without Schollership by seruing seauen yeeres apprenticeship, it is very rare, and by so much the more commendable where it is to be found. But to say something of all these particulars (because a Physitian is not alwayes at hand) will not be amisse I thinke for the information of such especially who when they know a little will be desirous to learne more.

First therefore for diet: Hot and sharpe or biting things the Patient shall forbear, as wine, strong drinke, spices, salt, onyons, &c. for such do attenuate and rarifie the humors, and make them more prone to influxion. Againe, let his diet be very thinne and slender, that so the influence of humors may be restrayned from the affected part, for an empty stomacke drawes from all the parts of the body, especially from those that are neere vnto it, and by consecution euen from the outward parts; whence it is, that the first dayes you shall doe best to diet this kinde of Patient very slenderly.

For purging, it is necessary to keepe the body soluble the whole time of the cure, so that it answer once a day at least; yet it is safer to do that by Clusters then by purgations, especially such as haue Scammonie or Colocynthis in them, or any other vehement ingredient, for the agitation of humours will produce a new flux.

For bleeding it is to be obserued, that vpon a wound with Gun shot, seldome or neuer any great flux of blood followes, especially presently, because through the greatnesse of the contusion, and the vehement agitation of the ayre, the spirits are driven inward. Yea if an arme or a legge be shot off with a peece of Ordnance, no great flux of blood will instantly follow, though diuers large Veynes and Arteries be broke. But afterward, to wit, about the fourth, fift, or sixt dayes, sometimes later, you shall haue a flux of blood; forsooth because by that time the spirits and the naturall heate rerurne vnto the part. Wherefore in the beginning you shall not neede to endeavour to stay the blood, but rather giue way to the issue of it, for the effusion of some good quantity of blood, will free the part from inflammation and fulnesse too: and if the wound do not bleede of it selfe, the Chirurgeon shall finde it fit to open a Veyne the next day after the wound is inflicted, and take away as much blood for depletion and revolution as the strength of the Patient will well beare.

Now for the mitigation of paine, the Chirurgeon must haue especiall respect thereto from the very beginning of his worke. And if paine be ioyned with inflammation (as most commonly it is) it may be abated by annoynting the neighbour parts with an vnguent made of Galts grease, nourished (as we say) with the iuyce of plantaine, houselecke, nightshade and the like.

like. The Vnguent also called *unguent. diachalciteos*, described by *Galen*, dissolved with vinegar, oyle of Poppy and oyle of Roses, is as effectuell as the former. In like manner *unguentum de bolo*, and many other of the same faculty. For although these be not properly *Anodynes* (which are all hot and moyst in the first degree) but cold, yet not narcotically, they will mitigate paine, because they correct a hot distemper, and doe stay sharpe and bilious fluxions, which are farre more impetuous then those that are cold.

After the vse of such Repercussives, it will be profitable to apply this following Cataplasme.

Recipe Mica panis infusa in Lacte vaccino libram unam & semis, bulliant parum. Addendo oleorum violar. & rosarum ana uncias tres, vitellos ouorum quatuor; pulueris rosarum rubrarum; florum chamemeli, & meliloti ana uncias duas, farina fabarum, & hordei ana unciam unam: misce, fiat Cataplasma secundum artem. You may also on the sudden make it with crummes of bread boyled with oxycratum and oyle of Roses.

Finally, for vulnerary potions, you may goe to our Dispensatory, or make them of Plantaine, herbe Robert, Doues-foot, Camphery, Dogges-tongue, Burnet, and the like. And so much of wounds made by Gunshot.

CHAP. XXIX.

Of wounds made with Arrowes, Darts, Iauelins and other such sharpe weapons.

Here is a great difference in the cure of wounds made with Arrowes and sharpe weapons, and those made with Gunshot. For the Bullet wounds alwayes with contagion, the Arrow or Iauelin, or the like, not so. Beside, the Bullet is seldome or neuer poysoned, the Arrow often. But among sharpe weapons there is great varietie which also makes the Cure various in some degree. I will not stand to enumerate the seuerall sorts of weapons, or make any curious diuision of them, onely I will exhibite to you in one figure a multitude of their fashions especially of their heads, which will be better then any description I can make of them.

The

Beside, you have here expressed the figure of a man wounded with all kinde of Weapons, and in euery part of the body.

Againe, there is great difference in respect of the wounded part, whether it be fleshie, bony, nervous, in a ioynt, or neere a ioynt, or farther off, in a noble part: as the Braine, the Longues, the Heart, the Stomacke, the Liuer, the Guts, or such like; or in a part more ignoble; in an inward or an outward part, and according to these differences, such wounds are more or lesse mortall. In all mortall wounds it shall be for the honour of the Chirurgian and his Art, to foretell the danger: Yet not to leave any thing vnattempted which may giue hope of recouery, because as in diseases, so in wounds, it falleth often out, that what the Physitian or Chirurgian giues over as desperate, that either some good old Wife, or which is worse, some cheating Mountebanke will take vpon him to cure, and if hee, while time, with a little herbe *Robert*, till Nature preuaile ouer the disease (which many times shee

doth aboue and against our expectation) then is he famed for a second *Asculapius*. Howsoeuer it is a great disparagement to a Chirurgian, if he be called while the Patient liues to let him die with the weapon in his body, yea as much honour may be gotten by the Artificiall getting out of the weapon in a desperate case, as by curing him that is not desperately wounded. It shall not therefore be amisse, a little to insist vpon the Artificiall extraction of such weapons.

And in the first place, the Chirurgian must be forewarned that he take care he doe not his worke butcherly, with too much cutting or tearing the flesh, but especially veines, arteries, nerues or tendons, leaſt it be said of him that his hand hath done more harme then the weapon, which would be an extreame dishonour to him and to his Art.

But to the matter. There be two wayes to get out a weapon: one by the way, it went in, and that we call extraction, the other by the part which is aduerse, and that wee call expulsion.

After the very first dressing, these workes must be done, and with more ease and felicity performed if you place your Patient in the same posture he was in when hee receiued the wound, as hath beene before signified. Againe, you shall haue at hand all your Instruments, as for example. A paire of Pliers whose handles when you presse together the shankes will be diuided; those are fit to take out an Arrow head, or the head of any weapon which is hollow, for the shankes being diuided in that hollownesse, will hold the Arrow head firme and fast, and so draw it out. The next is a hollow instrument of Steele like a Cane clouen in the length, in which runnes a slender and sharpe probe, and at the handle a large screw answerable to the hollownesse of the Cane of Steele: this screw doth not onely serue to diuide the clouen cane, which by that meanes fills the hollownes of the head of the Iauelin or such like, and so drawes it out as the former Instrument did, but also if a peece of the wood remaine in the head, it presses the sharpe probe into that wood, and so drawes it out.

The next is a paire of small plyers, a little compassed at the end, and toothed within; that if the wound be oblique it may attaine to the bottome of it, and meet with any small peeces of its mayle or the like, which lie there, and bring them away. The next is a paire of plyers, with a screw running crosse the shankes of the handle, but the end of the plyers is like the Crowes Bill, or a little flatter. This screw in the handle doth open and close the Crowes Bill, as you please to take hold of the head of the weapon, though it be buried in the flesh. Lastly, it may happen that some peeces of a Linke, of a Chaine, or mayle

be in the wound, and then you may vse a hooked probe to draw them out, and this instrument is also vifull sometimes in wounds made with Gunshot, where such rings or peeces of mayle are driuen into the wound. The figures of all these instruments, you haue hereunder expreffed in the order I haue described them, for in *Pareus* the descriptions are mistaken.

Now if the head of the Pike Iauelin or Arrow be broken off short and remaine in the wound, but not to be seene, or easily to be felt; yet you shall know where it lies by a roughnesse and inequality which you shall discerne by your probe. The flesh also will be bruised and appeare liuid or blackish, and the Patient will find a heauy paine in that part of the wound, though the weapons head be so bended in the place, that it do not alwayes pricke and goad him. As sometimes the stone that falles from the kidneyes, after it hath with wonderfull torment extended the vreter will be bedded therein, and goade no more till it moue againe: and yet the Patient will finde a heauy and grauatiue paine about the place where it resteth. Vherfore when any of these signes shall put you into suspition that some part of the weapon is remaining in the wound, vse your best skill and most proper instruments to finde it, and to draw it out. And if you must of necessity vse incision doe it as carefully as you can, and auoyd the vessels and tendons of the muscles, if it bee possible, which that you may doe your skill in Anatomy will guide you whereby you shall know what large vessels runne in any part, and where the tendons of the muscles are, and after you haue made such incision as is of absolute necessity, performe the other part of the worke which is to draw out the weapon with your toothed or rough Bills or Beakes, of which I haue before intreated. And this manner of incision you shall be most constrained to vse, when the head of the weapon is not plaine but indented, bifurcated or bearded like a crosse or broad Arrow, such as our *English* men shot of old out of Long-bowes, and now we vse to shoot at Deare. But heere you shall obserue the second manner of getting Arrows &c. out of a wound called expulsion; and that is, when either it pierceth so deepe, that it is neere the aduerse part, and with a small incision may there be drawne out, but cannot be extracted by the way it went in, without great difficulty; or when the head of the weapon is so forked or indented, that if it be extracted, it will rend and teare all before it. In both these cases it may be expelled or driuen out with your blunt or knobbed probe, at the aduerse part, you hauing by conuenient incision before, made way for it. And to say truth, beside the necessity of this impulsio, the conueniency of it will countervaille the incision, because when the wound is through and through, it will be more easily deterged and after consolidated.

But if the aduerse part to the wound, vpon which the head of the weapon doth rest be a bone; or if many tendons of Muscles or much flesh must be cut to make way for impulsio, as it hapneth in the brawny parts of the body; then you shall worke by way of extraction, dilating the wound first with the Instruments fit for that imployment, forbearing the Nerues and larger vessels as much as you can, according to your skill in Anatomy. With a dilatatorie hollow in the inside, you shall labour to comprehend both the beards of the

Arrow

Arrow head, or the like, and then with the Cranes bill before described, you shall take fast hold vpon it, and so drawing out both your instruments together, you shall together with them draw out the weapon head. The manner of this operation you haue deformed in this subsequent figure.

Obserue also that if the point of the weapon be fixed in a bone, you must gently shake it; gently I say, for feare you breake the sharpe point of it, & leaue it in the bone; and when you haue loosned it by such gentle shaking, then with the Crowes Beake, or the like, you shal endeouour to draw it out. When it is out you shall presse out the blood, as you may; and if much blood follow, you shall so far suffer the flux to continue as the strength of the Patient, and the condition of the affected part will permit; for so you shall secure it from a plenitude, and from a *Cacochymie*, and beside it will be lesse subiect to paine, inflammation, putrifaction, and such other symptoms as you feare might grow vpon you in the Cure. But if those symptoms ouertake you, then must you flie to the remedies before appointed.

Finally, although it be not vsuall that weapons should be poysoned, yet because the malice of men is sometime so exalted that they are bent vpon all mischief they can deuise, you shall learne to know when a weapon is poysoned, and how to behaue your selfe in such a case. You must therefore vnderstand that weapons are almost alwayes poysoned with hot poysons, seldome or neuer with cold. That they are poysoned with hot poyson, you shall perceiue as well by the propriety of the paine, as by the condition of the wounded flesh. For the paine, first it is beyond measure greater then the paine of wounds not poysoned. Secondly, whereas the paine of other wounds is most what grauatiue and dull, that which proceeds from hot poyson, is pricking, like the continuall stinging of a Bee, we call it a stinging paine. The wounded flesh will also discouer the poyson with a pallid and liuid colour, together with some signes of mortification, beside many other malignant symptoms which doe not vsuallly accompany wounds of a simple nature. In this case as soone as the wound is cleared of the weapon and all strange substances, you shall scarifie round about the wound frequently and deepe, and after set on Cupping-glasses, with a great deale of flame which may draw mightily, that the poyson may be exhausted: you shall also get them sucked by a man or woman whose mouth and pallat is sound and not vlcerrated, and you shall let him or her hold a little oyle in their mouthes least the poyson offend them. Lastly, you shall powerfully call out the poyson with Phenigmes, Vesicatories, Cauteries, and all other manner of outward applications which your Art shall suggest vnto you, which belong not to this place.

CHAP. XXX.

Of the nature of a Gangrene.

BEcause I haue oftentimes in the former discourse told you that wounds with contusion are subiect to Gangrenate, I resolued in this place to say something of that also, though I know this subiect would require a whole Treatise by it selfe; but I am onely at this time (as I haue often said) in the explication of Instruments, and if you meet with any other Tackling by the way which may serue your turne, vnderstand it to come in by the bye, not by the maine, and out of *Pareus* for the most part, as also all the rest.

A Gangrene therefore vpon a contusion, comes sometimes by the fault of the Chirurgicalian, sometime through the error of the Patient, sometimes from the vehemency of the contusion, but most commonly from the condition of the part affected; of all which wee shall vnderstand the causes better, if we first describe the nature of a Gangrene.

A Gangrene therefore is a disposition and way to a mortification of the part wherein it is, which creepeth vpon it by degrees; and when it is consummate it is called *Sphacelus* by the *Grecians*, by the *Latines*, *syderatio*, we say such a part is mortified.

The most generall cause of a Gangrene is the dissolution of the Harmony and conternperation of the foure first qualities whereby the part is made vnfit to receiue the spirits

and faculties, as well naturall as vitall and animall, by which it is nourished, by which it liues, moues, and hath sensation; for if a part be depriued of these influences it presently languishes and shortly after dies.

The Primitiue or externall causes hereof are combustions made by things which are either actually or potentially fiery. Actually as Fire it selfe, scalding Oyle or Water, Gun-powder fired and such like. Potentially, as biting and goading Medicines, put case sublimated *Calcanthum*, and Potentiall Cauterics; for all these raise a mighty inflammation in the part. In like manner vehement perfrigerations by the ambient ayre may bring a Gangrene, as also the vnseasonable vse of cold and Narcoticall Medicines. Moreover, a Fracture, a Luxation, a notable Contusion, as I said before, Ligatures, if they be too hard and fast; the bytings of mad or poysonous beasts, the pricking of a Nerue or Tendon, the wounds also of neruous parts and of the ioynts, especially if the body be *plethoricall* or *cachymicall*: Finally, large and deepe wounds wherein the larger veines and arteries are cut asunder. For all these causes doe more or lesse, sooner or later, dissolve the harmony of the first qualities before mentioned, if the mischiefe be not seasonably preuented.

The internall and (as we call them) Antecedent causes of the Gangrene, are the plentiful confluences and defluxions (and those sudden) of hot or cold humors vnto a part. For the faculty of the part being not able to gouerne them, it commeth to passe, that the inbred heat for want of transpiration is suffocated and extinguished. For by this defluxion the Arteries are so straightned, that they cannot dilate and contract themselves by ordinary pulsation, whereby the naturall heate is cherished and contempered. But then especially is the Gangrene most incurable when that defluxion of humors, seales first vpon the bone and from the bone the inflammation takes his originall. Yea, the bone is not onely first inflamed (I meane the *periostion* which couers it) but also the very substance of the bone is at the first hand tainted with a caries and rottenesse, as in the *French* disease and the *Le-prosie*; especially in the *French* disease you shall haue a mans flesh plumped and sound, and his skin faire and smoothe, and yet his bones rotten, and as it were worme-eaten. And this alwayes from a venemous matter which lies dogging and gnawing vpon the bone. And this poysonous matter is sometimes hot, as in Plague-sores which will Gangrenate now and then within two houres; sometimes it is a cold poyson, as the poyson of the Pox (which is not so quicke) and other secret poysons satling in particular parts, whereof out of *Pareus*, I could giue diuers instances, one of mine owne experience you shall haue. A Gentlewoman of *Norfolke* made great cōplaint to me of a paine in her forehead, yet there appeared no inflammation or tumor, within two or three dayes in the middle of her forehead appeared three blew spots as big as Pease, and in other two or three dayes, they grew blacke but no bigger, and the mortified flesh fel out to the very skull, & suddenly healed vp againe without any more trouble. I perswade my selfe this sudden mortification could proceed from no other cause but some poyson, which issued out at the Commissure of the skull, which is called the sagittall suture, and in women diuideth the bone of the forehead.

I say not that such a sudden Gangrene cannot proceed from any other cause but from poyson. For it is not extraordinary, that it should come from the temerarious vse of Narcoticall medicines, sometimes also from the keene and penetrable cold of the ayre in Winter, whereby the spirits and naturall heate of a part is vtterly extinguished, and the influent heate beaten backe. For when a part is so frozen, the influent heate cannot pierce it, or if it doe, it cannot remaine in it, but is beaten backe or arrested and put out. Note here that the Gangrene which proceeds from extreame cold, doth especially occupy those parts which are farthest off from the heart which is the source of heate, as the feet and the hands, or else those parts which are of their owne temper cold, as the gristles of the eares and the nose.

CHAP. XXXI.

Of the signes of a Gangrene.

He nature of a Gangrene thus explained, we come to the signes. If therefore it proceed from an inflammation or phlegmony, the paine and pulsation will cease, without iust cause, that is to say, without resolution, suppuration of the tumor, and the flaming and ruddy colour of the part will suddenly grow browne or liuid. By pulsation here I doe not meane onely that beating which

which proceedeth from the distempered Artery, but that dolorous beating which is begotten by the contention betwene the naturall and preternaturall heates, which contention proceedeth from certaine crasse vapours arising from the humors which the Gangrene shuffeth vp and downe and setleth a bad impression vpon. If the Gangrene proceed of cold, then presently and vpon the sudden, an acute pricking and burning paine inuades the part; for, penetrable *frigus adurit*, as the learned Poet saith. Another signe is, if the flesh and bright rednesse of a part, such as will appeare in a mans hand that rowles a Snow-ball, be suddenly turned liuid and wanne. Againe, if in stead of an extraordinary heat that was in the part, presently it becomes cold, nummed, stupid, and that not without a sensible horror, as if it were seased vpon and shaken by a cold fit of a quartaine Ague. If this cold increase so farre that it vtterly extinguish the naturall heate, then a mortification will follow vpon that Gangrene; and beside, oftentimes convulsions and violent contusions of the whole body, whereby the braine and the vitall parts are grievously disquieted.

Those Gangrenes which come vpon too hard Ligatures, vpon Fractures, Luxations, and contusions haue alwayes an hardnesse accompanying them, which is caused by attraction and incurfion of humours. Many times certaine pustules and blebs rise vpon the skin confining, which are caused by a notable ardor not farre from a degree of combustion. The member also Gangrenated, is more heavy and weighty then of due it ought to be, because there is want of spirits to ballance and poyse the Moles or mountenance thereof, and to support it. Againe, if you presse a gangrenated part, somewhat hard with your finger, it will leaue a print and footstep behinde it, as it doth in an *Oedema*, proceeding from the drop sic, or the like disease. Finally, in a Gangrene, the skin without any iust cause, will easily shire from the flesh, yea, sometime the whole and true skinn, not the cuticle onely.

If the Gangrene proceed from the biting of a mad Dogge; or of any other venomous Beast, the pricking of a sinew, the breaking, as it is called, or rather the extension of an Artery called *Aneurisma*, or from some notable wound in a phlethoricke body, or which is oppressed with a *Cacoehymia*; or in a part of exquisite sense; all these Gangrenes shall bee discerned by the same signes, by which we discerne a Gangrene proceeding from inflammation, of which I spake before. For these and the like causes, doe cause attraction, and fluxion of humours, into a part more then the ingenie of the part will beare, or can moderate and regulate, and so perspiration being intercepted, and the pores stopped, there followes necessarily an oppression and suffocation of naturall heate and a Gangrene, which are tearmes convertible.

Here saith *Pareus*, I would admonish the yong Chirurgian (he might haue put in all) that when from these signes before named, he knowes the place is Gangrenated, and that a Necrosis or mortification will follow (for that I presume is his meaning) that he doe not protract time, but as soone as he can prepare himselfe and his Patient, that he proceed to Amputation or dismembring, although there remaine some sense in the part, or some small motion. For oftentimes in this case, the member is not moued by the motion of the whole muscle, but haply the head of the muscle is not yet gangrenated, which sound head, whilest it moueth it selfe, it also moueth the tendon or taile of the muscle which is continuall with it although it be already mortified. Wherefore to delay in such a case is dangerous. But of this we shall speake further by and by. In the meane time, I will adde something of the Prognosticke, which a Chirurgian ought to giue vpon a Gangrene. For, as in all other desperate Cures, it becomes him well to declare the danger his Patient is in, to secure his owne reputation, and to asser the honour of his Art, which lies at stake as well as his credit. So especially in the case of a Gangrene, the rage and malignity of which disease, is so great, that it will out of hand, not onely kill the part affected; but by contagion also sease vpon the neighbour parts, and in time vpon the whole body. For a Gangrene is a very poyson which turneth all it meets with into his owne nature, or if you will, like fire (though not so like) it eats, feeds vpon, and depopulates whatsoever comes into his way. Againe, *Hippocrates* in his booke *De vulneribus Capitis*, saith; *There is no proportion betwene the Liuing and the Dead*. And therefore you must say, that the dead part must presently be separated from the liuing, *Ne pars sincera trahatur*. Moreouer, when your Patient shall haue a cold sweat arise vpon his whole Body, when a *delirium* takes him, and that he cannot sleep, when the Hickocke and abrupt belchings come vpon him; finally, when he is overtaken, with frequent returning, faintings and sowndings, then you may prognosticate, that death is at the doore. For all these symptomes are caused by vapours which arise plentifully and

perpetually from the corruption and mortification of the humors and the flesh, through the veines, arteries and sinewes, vnto the noble parts. Finally, when thou hast thus provided for thy owne reputation, and the honour of thy Art, by acquainting the friends of thy Patient with the danger; then if thou finde any hope at all of curing or intercepting the progresse of the maladie, hasten to thy worke.

CHAP. XXXII.

Of the Cure of a Gangrene curable, before it come to perfect mortification.

He Indications of curing Gangrenes, are taken from their variety, the variety I meane of their essence and magnitude. For some Gangrenes occupy a whole member, others onely a part of a member; some are profound and deepe, others outward and superficially. The state of the body is also to be considered: for soft and delicate bodies, as are the bodies of Children, Women, Eunuches, and those that liue idly, doe require more milde and gentle medicines, then those bodies which by Nature, Custome, and Trade of life, are stronger and harder, as of Husbandmen, Laborers, Marriners, Huntsmen or Hunters, Porters, and such like; who liue thriftily and courselly. Againe, there is consideration to be had of the affected part, for there is a difference to be made betweene the Cure of a Gangrene in a fleshy and musculous part, and in a solid part, as those which are neruous, and in, or about the ioynts or the bones. Moreover, such parts as are hot and moist, as the secret parts, the mouth, the wombe, and the fundament, are more easily and sooner tainted with this manner of corruption, and therefore you may sooner apprehend the danger, and consequently with more speed set vpon the Cure. And first of all if the Gangrene proceed from inward causes, you shall call for the aduice of a Physitian to prescribe his dyet; as also if the body be Plethoricall or Cachoymicall, to aduise concerning Letting of Blood and Purgings. The heart also must be fortified and corroborated to defend it against the Transfusion of vapours arising from the affected part, by inward Cordials, and outward applications, as Epithemations, and the like. All which I leaue to the care of the Physitian.

But if the Gangrene proceed from a plentiful influxion of blood or humors, as vpon a great phlegmone, or the like, the cure shall be begun by euacuating and drying vp of humor which haue putrified in the pained part. To this purpose, you shall vse scarifications and incisions, deeper or more superficially, as the condition of the Gangrene shall require, that the part being so exonerated, may haue the benefit of perspiration, and the concluded humours of distillation, and vent made for the fuliginous and sooty excrements which abound in it.

Incisions you shall make with the Phlegme or Penknife, deepe and manifold when the Gangrene is great, profound and neere to mortification: As when it reacheth neere the bone: yet you must haue great care to auoyde the most notable Nerues and Vessels, vnlesse they be vtterly mortified, and make your sections in the distances betwixt them. If the Gangrene be lesse, you shall be contented to vse onely scarifications. For this purpose *Pareus* hath an instrument which he calleth the *Scarificator*. It is a box wherein are fastened many rownd wheelles as it were, sharpe as phlegmes, which by a handle fitted into the side of the box are made to strike all together, so that with this instrument you shall make as many scarifications at once as the phlegme will doe at many times, and beside all of one depth. The instrument with the couer is hereunder expressed.

When

When scarification is thus made, then shall you foment the part with wine-vineger, wherein you shall boyle Radish rootes, the rootes of *Serpentaria maior*, of *Arum*, and *sigillum Salomonis*, *Auripigmentum* and the like. For these sharpe medicines doe powerfully warme, resolue, and draw the clodded blood from the bottome into the skin, which otherwise will interclude the passage of the spirits, whereby the integrity of the part is preserved, and beside extinguishes the naturall heate. But in this administration you must be very cautious, least together with the clodded and grumous blood, you draw also the blood out of the veynes. Againe, you must be carefull you vse not these drawers till you be sure the influxion of blood is stayed. If the contusion be but small, you shall dissolue Virgine waxe with Cumine seede, Cloues, and the roote of our Ladies scale. The Emplaister which followes doth powerfully discusse grumous or clodded blood.

Recipe Picis Nigrae uncias duas, Gummi Elemi unciam unam semis, Syracis liquida & Terebinthina com. ana semi-unciam, pulveris sulphuris vivi unciam unam, Liquefiant simul, fiat Emplastrum, extendatur super alutam.

Sometimes you shall finde that vpon scarification the blood will issue freely of it selfe, suffer it on Gods name so to doe, till you thinke the part is well vnburthened, then foment it with medicines which will warme, dry, resolue, deterge and open, all which faculties will chaunce and correct the putrifaction. Let them also be penetrant to consume the virulence which is infixed. For that purpose make Lotions of the Lee which is made of the Ashes of the Oake, wherein you shall boyle *Lupines* till they be very tender. Or for more expedition, take salt water and in it boyle *Aloes* and *Agyptiacum*, and adde a little *aqua vita* in the end of the decoction, for *aqua vita* and *Calcanthum* burnt into ashes, are singular remedies for the Gangrene. Or,

Recipe, aceti optimi libram unam, mellis Rosati uncias 4. Syrupi acetosi uncias tres, salis communis uncias 5. bulliant simul, adde aqua vite semilibram. Wash the part often with this water, for it is of great vertue to inhibit the spreading of a Gangrene. After this washing you shall lay on pledgets with *Agyptiacum*, and also with your Probe presse them into the incisions if you haue made any, and that will meruailously repress putrifaction, and inducing an Eschar, will separate the rotten flesh from that which is sound. For in this case you must not expect till the rotten flesh separate of it selfe, but if you perceiue any part of it to bee corrupted, you shall with your knife or sheeres cut it off; after put in *Agyptiacum* as often as neede shall require, and how often neede shall require you shall discern by the colour, smell, and sensibleness of the flesh. The *Agyptiacum*, whose vertue I haue often proued admirable, saith *Pareus* in such cases, is thus made.

Recipe, floris eris, Aluminis Roch. mellis communis ana uncias tres, aceti acerrimi uncias quinq., salis Com. unciam unam, vitrioli Romani semi unciam, Sublimati pulueris, arachnas duas, bulliant omnia simul ad ignem, fiat unguentum.

After you haue intimated the *Agyptiacum* into the incisions, lay on the following *Cataplasme*, for it stops putrifaction, it resolues, deterges, dryes vp the virulent sanies, and by reason of the dry tenuity and subtilty of the parts of it, it pierces deepe into the member, corroborates it, and beside, it is an *Anodyne*.

Recipe, Farina fabarum, hord. prob. Lent, lupi. ana semilibram, salis com. & mel. rosat. ana uncias quatuor, succi absynthij, marrub. ana uncias duas semis; aloes, mast. myrrha & aqua vite, ana uncias duas, oxymelites simp. quantum sufficit: fiat Cataplasma molle secundum artem. Aboue the Gangrene you shall lay this defensatiue to repress the influxion of humours into the part, and the vapours from ascending from the rottenesse into the whole body.

Recipe, Olei rosati & Myrtillorum, ana uncias quatuor: succorum plantag. solani. semper-vivi, ana uncias duas, Album. ouorum quinque, Boli Armen. terra sigillata subtiliter pulueriz. ana unciam unam; exygerati quantum sufficit: misce ad usum dictum. All these applications must be oftentimes renewed: But if the disease be so stubborn that it will not yeeld to the medicines aboue described, then you shall proceede to Cauteries; after the application whereof *Galen* commandes that you apply the iuyce of Leekes wherein beaten salt shall be dissolved. This is a penetrating and desiccating medicine, and therefore is avaleable to resist putrifaction.

If the Cauteries do no good, then must you arise vnto the extreame remedy of all, and that is amputation of the Gangregated part; but first bee sure you vnderstand sufficiently that the part is mortified, for it is no small error if vpon your mistake a man lose a member vnneccessarily. Wherefore before I come to the manner of Amputation, I shall breefely set downe the signes of perfect mortification.

CHAP. XXXIII.

Of the Signes of a perfect Necrosis or Mortification, and of the place where you should dismember.

That the Gangrene is become a *Sphacelus*, and that the part is vnterly mortified and dead, you may know assuredly, if the colour of it be blacke, and if it bee cold to feele to, and yet the weather not frostie: if it be very soft, so that the part of the flesh which is pressed downe with the finger doth not rise vp againe but leaues the print of the impression behinde it: if the skinn come from the flesh vader it; if it exhale so odious a stench (as it will doe, especially if the *Sphacelus* be vicerated) that those which stand by cannot indure it. If a sanious liquor thicke, Greene or blacke issue from it, if the part haue neither motion nor sence, when it is shaken, strooken, pricked, burnt, or cut. But here I must aduise the young Chirurgian to be circumspect that he be not misguided in his opinion concerning the want of sence in the part Gangrenated. For the Patient who was vsed to extreame paine in the part before it was mortified, will after the mortification vpon that remembrance, complaine as much if it be pricked as he did before, but you must know that this is a false sence, and proceedeth rather from the strength of imagination then because there is any true sence in the part. That this is so appeareth most plainly, sometime after the amputation of the member, for they will a good while complaine of the paine of the part after it is off: yea it hath beene knowne that some Months after the leg was dismembered, the Patient hath complained of the paine of that leg. This is a strange thing and hardly to be credited were it not for the eye and eare witnesses who haue avouched it. Wherefore when the signes before remembred shall perswade you to take off a part, let not the conceit of your patient cause you to protract time lest the whole body bee drawne into Contagion and so the opportunity of sauing a mans life and of magnifying your Art be forfeited.

Yet before I come to the manner and Art of amputation or dismembring, there remains one thing of great Consequence to bee discuffed, and that is in what place of the member the dissection ought to bee made, for herein will consist a great part of the Chirurgians reputation. Your Art commands that you should in amputation touch that part which is liuing and make your incision in sound flesh. Againe the same Art Commands you that (as much as it is possible) you should preserve the liuing part of the member. To cleare this difficultie *Pareus* giues an instance. Suppose the foote bee Sphacelated as high as the ankles, where will you dismember &c. For vnlesse you take hold of the liuing flesh, though you forbear neuer so little of that which is mortified, according to the nature of poyson (as I sayd before) the mortified flesh will by contagion gaine by degrees vpon the whole body and turne all into his owne corruption, wherefore you shal rather cut off a little of that which is sound then leaue neuer so little of that which is mortified. Notwithstanding it hapneth sometimes that the more commodious vse of that part remaining, some times the decencie will perswad you to take off more of the liuing part then the necessitie of the *Sphacelus* doth require. As in the case before named you shall make your amputation five-fingers bredth below the knee. For so the patient shall be able to vse the rest of his legg better: otherwise if you dismember as neere the ankles as the life of the legge will permit, the Patient will bee more troubled in his gate. *Pareus* names a Capraine whose leg about the ankle was shot off in a sea fight. The wound was healed; yet was the long stumpe so troublesome to him that hee caused it againe to be cut off five fingers vnder the knee, and then with a wooden leg he was able to moue nimble all his life after. But if such a chance should happen in the arme, you must not do so, but preserve as much of the liuing part as you can, for a man goes not vpon his armes or hands, as he does vpon his feete and legs.

CHAP. XXXIII.

Of the Art and manner of dismembring.

In the Art of dismembring, the first consideration to be had is of the strength of your Patient; wherefore you shall consult with the Physitian to nourish him with meates of good inyce and of easie concoction and which breede many spirits, as the yolkes of egges, bread tosted and put into good wine. Then you shall place him decently and securely and gather vnto the sound parts of his body, and then binde the part

part with a fast and some what painfull ligature, a little aboue the place where the incision shall be made, and the band shall be strong and somewhat broad like a womans fillet. This ligature hath a threefold vse: the first is, that it holds the muscles together with the skinne somewhat vp, which after the worke administred falling downe, couer the extremities of the diuided bones; and after the Cicatrice is induced, become like a quishion to keepe them from offence: adde herevnto, that by how much more flesh and skinne there is about the extremity of the bones, by somuch the sooner will the Cicatrice grow vpon them. The second benefit of the ligature is, that it prohibits the flux of blood by compressing and intercepting the continuitie of the veynes and arteries. The third is that it brings a stupor vpon the part, and takes away for the time that quicknesse of sense which otherwise it would haue, by intercluding the passage of the Animall spirits, so that the Patient fees not the paine of the incision so much as otherwise he should.

When the ligature is thus fastned and the sense of the part therewith a little nummed, then with such an instrument as is herevnder described, made keene and sharpe for the purpose, you shall suddenly circle the flesh about to the very bone.

A hooked knife fit to dismember with.

Note here that sometimes among the bones there lies some parts of the muscles which you cannot easily come at with this instrument, nor with an incision knife. If there be any such, you shall diuide it as well as you can, and separate it from the bone, because if you leaue it to be diuided

from the bone by the Saw, you shall put your Patient to great paine, for the saw will be cloyed therewith.

As soone as you come to the cleare bone, set on your Saw, which shall bee made after this manner, and about fiftene inches long.

The Figure of the dismembering Saw.

A stroke, two or three (if the Saw bee good) will dispatch the businesse, and then you shall haue a fine Raspe in a readinesse, wherewith you shall leuigate and make smooth the asperitie and roughnes which the Saw made vpon the bone.

The flux of blood which shall follow the operation, you shall not suddenly stay or inhibite, but suffer it to flow according to your Patients strength, that the part may be lesse subiect to inflammation and other symptomes.

When you would stay the blood, you shall with this instrument which is most like the Crows beake, apprehend the ends of the vessels which you shall finde among the flesh of the muscles; and it shall not matter much though with the vessels you comprehend with your instrument some of the flesh also; for there will follow no danger vpon it but rather a profit, because the flesh will helpe to consolidate the vessels.

The Crows Beake to draw the vessels out of the flesh, that they may be tyed up to stay their bleeding.

When

When you have so gotten hold of the vessels with this instrument, you shall tye them with a double and strong thred, and then loosen the Ligature you make above the place of the amputation: next with a sharpe needle and a thred, you shall with foure stiches, but taken deepe into the flesh, and crossed asslant like the letter X, sew vp the flesh and the skin somewhat loosely to couer the end of the bone, that it take not the ayre. For if you should endeouour to draw it close, and make the skin meet, your stiches would breake, and your worke would be interrupted; beside, way must be left for some quittance to issue, or else the wound will not heale.

But if by chance, or for want of care, any of the vessels which you tyed be loosned, then you shall againe cast on your Ligature with the fillet about the incision, as you did before, or else let your seruant with both his hands so compresse the member, that his fingers may stop the flux of that loosned vessell, which he may well doe if you haue skill in Anaromy. Then shall you your selfe haue a needle ready about foure inches long, square, and with sharpe edges, and in it a strong thred three or foure double, with which you shall knit the loosned vessell. After this manner as I expresse *Pareus* his relation. First, you shall marke where the vessell lies, and enter your needle on the outside of the flesh, opposite to it, and somewhat deepe, but halfe a fingers bredth, wide on one side, and guide your needle obliquely toward the vessell, that it may issue againe immediately beyond the orifice of it; then enter your needle againe within lesse then a strawes bredth where it first issued, and guide it obliquely vnder the vessell through the flesh (somewhat deepe likewise) and issue it a whole fingers bredth from the place where the first stich entered; so shall you haue the two ends of your thred on the outside of the flesh, and a fingers bredth distant. In that distance, you shall lay a pledget of a fine ragge, twice or thrice double, and then knit the ends of your thred in a fast knot vpon the pledget, straining them a litle, and that straining will so comprehend the vessell that it cannot bleed. Beside, the pledget will keepe the knot from penetrating the flesh, and you shall not doubt but the mouth of the vessell will grow quickly together with the flesh, that there will be no feare it should grow againe. Or if a few drops of blood fall, you shall be assured they come not from that, but from some other small vessell which will also be easily inhibited by the application of those adstringent medicines which we shall in the next place speake of.

CHAP. XXXV.

What the Chirurgian must doe after the member is cut off.

Irst, he shall strew vpon the wound an Emplasticke poulder, and vpon it a pledget of dry Lint. The Poulder shall be thus made. *Recipe Boli Armeni uncias quatuor, farina velatilis uncias tres, picis res. uncias duas: in pollinem omnia redigantur & ex mixtis fiat puluis.*

When you haue thus dressed vp the wound, in the next place you shall provide a defensatiue for the member, which may repell the concourse of humours which otherwise would flow to the wounded part, and that you shall make in forme of an vnguent, after this manner.

Recipe Albumina ouorum vi. boli armeni, sanguinis draconis, gypsi, terra sigillat. aloes, mastis: Gallarum Comb. ana uncias duas: in pollinem redigantur omnia & bene agitentur addendo ol. rosarum & mirti: ana unciam vnam: fiat defensivum ad formam mellis.

This vnguent shall be administred with stupes moistned with *oxycratum*, which stupes shall be so large, that they may not onely couer the member it selfe, but also the neighbour-parts. As for example. If the Leg be dismembred in the place I before mentioned, yet you shall lay your defensatiue to the top of the knee; yea, & about it to, it will not be amisse, for this medicine is not onely repercussive, but it wil also strengthen, it will contemper the blood, ease paine, and preuent an inflammation.

It will be profitable also to couer all with double cloathes and swathes, wet in *oxycratum*: which done, you shall lay the member at as much ease as you can, vpon a Cushion not filled with Feathers but with Branne which will hold it vp steady in the posture you place it in. This first dressing you shall not stirre of foure dayes, if it be in Winter; in Summer not of two dayes, vnlesse there be great necessity. As for the tyes wherewith you knit vp the vessels, you shall not stirre them at all till the flesh be growne vpon the orifices of the vessels. Which you shall hasten with this poulder, which is refrigerant, adstringent and emplastickall.

emplasticall. *Recipe Boli armeni, farina hordei, picis ref. Gypsi, ana uncias duas. Aloes, nuoum cup. Cort. gran. ana semunciam: incorporentur omnia simul, fiat puluis subtilis.* Strew it vpon the whole wound for three or foure dressings, then onely vpon the vessels, and that doe eight or tenne dressings, till you be past feare that they should bleed againe. In the meane time vpon the rest of the wound you shall apply a digestiue, till it become purulent, that is, till you perceiue the quittance to succeed; then you shall forbear the digestiue and apply *detergents* and *mundificatiues*. Such as this is which followes.

RR. Terebint. Venete Lota in aqua vite, uncias tres, mellis ros. Colati unciam unam semis, succorum plantag. apij, Centaurij minoris ana unciam unam, bulliant omnia simul ad consumptionem succorum, auferantur ab igne addendo, farina fabarum & hordei ana semunciam Theria. Gal. drachmas duas, aloes, myrrha, Arist. ana unciam unam semis, Croci semi scrupulum, fiat mundificatiuum.

I said before, that it is ordinary for the Patient, long after the member is cut off to imagine he yet hath it, and that he feelles paine in it. Now you must know that this is not altogether without cause. For the nerue or sinew which is cut in sunder contracts it selfe towards his originall, and that contraction induces a paine much like a convulsion. For as *Galen* writeth in his booke, *De motu musculorum*, the proper action of a nerue and a muscle is contraction. Their tension is not so much an action as a motion. Wherefore you may ease that convulsive paine, by anointing the ridge of the backe, and the whole member also, with this following Liniment.

Recipe, Salvia, Chamepytheos, Maiorana, roris marini, mentha, ruta, Lanendula ana m. i. Florum Chamemeli, meliloti, summitatum Anethi & hypericonis ana: p. ij, baccarum Laur. & Iuniperi, ana uncias duas, Rad: Pyrethri drachmas duas, Mastich. Asa odorat. ana unciam unam semis, Terebint. Venete libram: olei Lembr: anethi, Catellorum ana uncias sex, olei Terebint. uncias tres, Axungia Hum: uncias duas, Croci drachman unam, vini albi odoriferi Libram, Cera quantum sufficit, conuendenda contundantur, puluerisanda pulueriscentur, deinde macerentur omnia in vino per noctem postea coquantur cum oleis & axungia predictis in vase duplici, fiat Linimentum secundum ariem. In fine adde Aqua vite drachmas tres.

In the meane timewhilest your Cure thus proceedeth, you shall haue a diligent respect to the scaling of the bone or bones which your Saw touched, and the aire tooke in your operation, for they must scale. You shall therefore at conuenient time, with an actuall Caustery, that is, with a hot iron seare them so carefully that you touch no part of the flesh or the vessels; neither must you much hasten the scale away, but moue it lightly now and then, and commit the rest to Nature, which haply will shoot them within thirty dayes after the dismembring, it may be later. Finally, after all this is done, when there arises any proud and spungie flesh, you shall sneape and prohibite it with Catheretickes, as *Caleanthum verum, puluis Mercurij*: and the like; especially boyled (or as we call it) burnt Alum in poulter, is excellent in this case, whether you vse it by it selfe, or mingle it with the rest.

This Course you shall continue till the wound be healed, and the Cicatrice bee growne vpon it: altering your medicines as your discretion, and the condition of the wound shall aduise you, according to the Method before proposed.

CHAP. XXXVI.

Pareus his Reasons, why for the staying of the blood, when a member is cut off, he doth not vse the ordinary way of Cauterizing with the hot iron, but this which we haue before related.

Confesse (saith *Pareus*) that I was wont to stay the Flux of blood which followed vpon dismembring after another manner then I haue before set downe, but I am sorry and ashamed that I haue so done, yet I therein followed the practise of my Masters and Teachers, who thought themselues sufficiently furnished to stay a flux of blood when they were provided of hot Irons and Causticke Medicines which they might vse at their discretion. Now I cannot remember my former practise without horreur. For it put my Patients to insufferable paine, because the operation was administred vpon liuing and sound flesh, whose sense is most exquisite. Neither indeed can any Causticke be applied to a Nervous part, but the vehement impression of the fire, will be suddenly communicated to the *Viscera* or noble parts, wherupon must needs ensue many dire symptoms and oftentimes death it selfe: For in my account, saith *Pareus*, I haue scarce knowne, that the third part of such as haue been so dealt with, haue escaped, and those not without great difficulty;

difficulty: because those wounds which are burnt or seared, are very hardly brought to a Cicatrice, for the burning stirres vp insufferable paines, from whence come Feauers, Convulsions, and the like, or worse accidents. Adde hereto, that after a Causticke, when the Eschar falls off, there often happens a new Flux of Blood, and then the Causticke must bee applied againe; which is to torment the Patient, not onely with an insufferable, but with an often returning paine, in the application of the Causticke, iterated againe and againe, by which repetition, the fleshy and neruous substance of the part, is by degrees consumed, and so the bones laid bare; so that diuers such Patients could neuer get a Cicatrice to grow vpon the wound, but haue carried an Vlcer in the place where the member was cut off, all the dayes of their miserable life. Beside, where such an Vlcer is, it is not possible to weare an artificiall Arme or Legge, which we see many doe, so cunningly adaped that it cannot easily be discerned by others, nor very much missed by him that wants it. Wherefore, faith *Pareus*, I earyestly intreat all Chirurgians, that then would (being admonished) giue ouer that cruell and Butcherly kinde of Curation, and Practise this which I haue prescribed, taught me, as I interpret it, by the suggestion of some good Angell. For I neither learned it of my Masters, nor of any other man, onely I read in *Galen*, in the fift Booke of his *Method*, that to stay a Flux of Blood, there is no remedy so present as to tye vp those vessels that bleed toward their roots, that is, toward the Liuer and the Heart. Now I conceived that this doctrine of *Galen*, for the binding and sewing of Veines and Arteries in fresh wounds, might well be vsed in the like vessels after a dismembring, and therefore I put it in practise; yet so that in the beginning, I had alwayes Cauteries and hot Irons in a readinesse, that if my proiect sayled, I might flie to my abhorred, but necessary reliefe. But when I had the experience of the facility, and the felicity of the course I now hold in a multitude of my Patients, then I had an eternall adue to Causticke and hot Irons in this operation. And thus I wish all Chirurgians to doe. For it is not in our Art as it is in Ciuill affaires that Prescription, Law, or Authority should preuaile ouer right reason.
